1 Memory and bus architecture

Memory and bus architecture

1.1 System architecture

The main system consists of the following parts:

- Two drive units:
  - CPU system bus(S-bus)
  - Generic DMA
- Three passive units:
  - Internal SRAM
  - Internal flash memory
  - AHB to APB bridges(APBx), connecting all AHB devices

They are interconnected through a multi-stage AHB architecture, as shown in Figure 1.

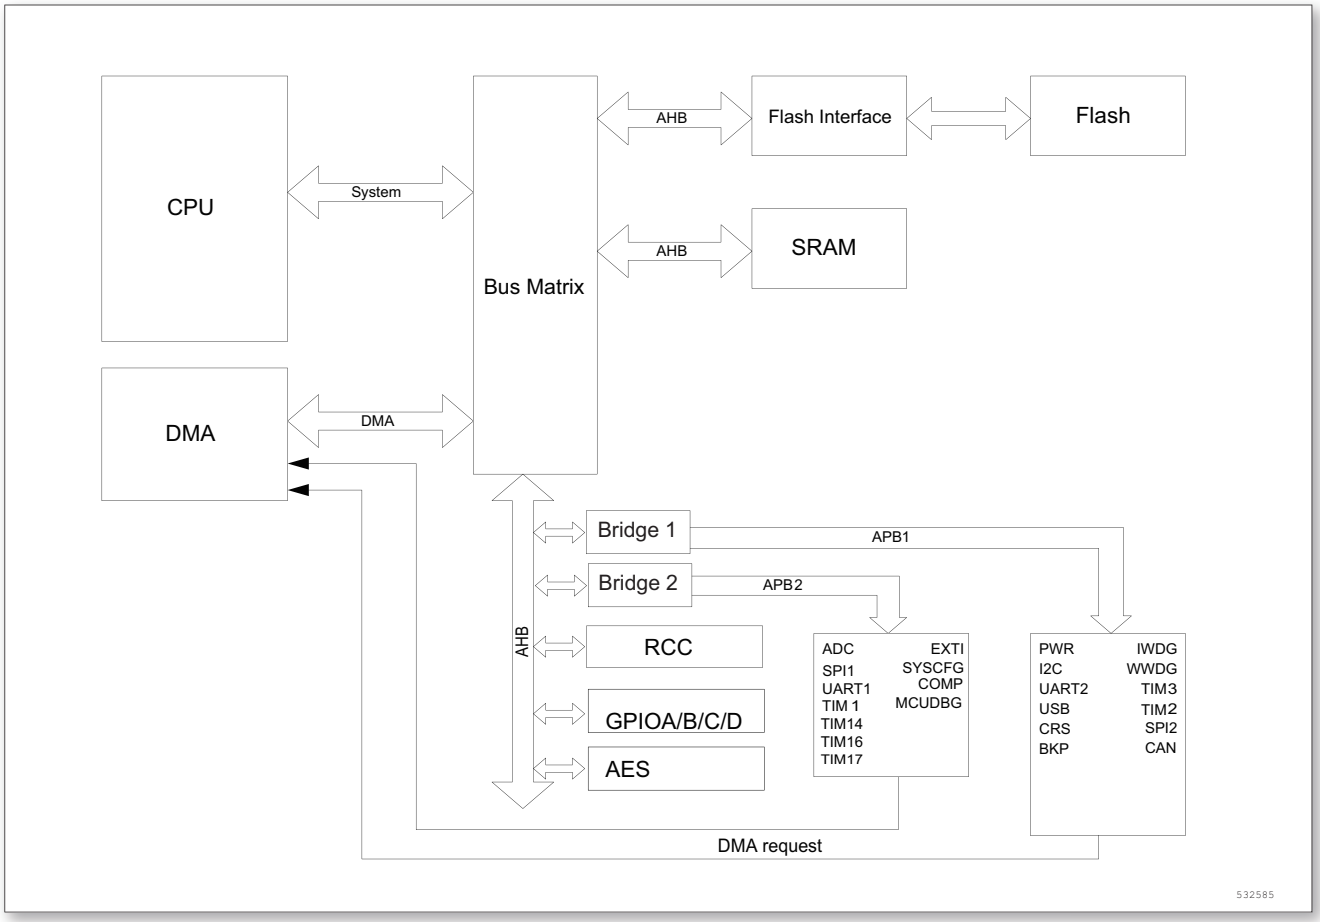

Figure 1. System architecture

System bus

The bus connects the system bus (peripheral bus) of the CPU core to the BusMatrix, which manages the access between the core and DMA.

DMA bus

The bus connects the AHB master interface of DMA with the BusMatrix, which manages the access of CPU and DMA to SRAM, flash memory and peripherals.

BusMatrix

The BusMatrix, composed of master module bus and slave module bus, manages the access arbitration between the core system bus and the DMA bus.

AHB peripherals are connected on system bus through a BusMatrix to allow DMA access.

AHB2APB bridges - APB

The AHB-APB bridges provide the synchronous connections between the AHB and APB bus. After each device reset, all peripheral clocks are disabled (except for the SRAM and Flash). Before using a peripheral, you have to enable its clock in the RCC_AHBENR, RCC_APB2ENR or RCC_APB1ENR register.

note:When a 16- or 8-bit access is performed on an APB register, the access is transformed into a 32-bit access: the bridge duplicates the 16- or 8-bit data to feed the 32-bit vector.

1.2 Memory organization

1.2.1 Introduction

Program memory, data memory, registers and I/O ports are organized within the same linear 4-Gbyte address space.

The bytes are coded in memory in Little Endian format. The lowest numbered byte in a word is considered as the word's least significant byte and the highest numbered byte the most significant.

The addressable memory space is divided into 8 main blocks, each of 512 MB. All the memory areas that are not allocated to on-chip memories and peripherals are considered "Reserved". Refer to the section 1.2.2 and Peripherals.

1.2.2 Memory map and register addressing

See the memory map in Peripherals chapters.The following table gives the start addresses of the embedded peripherals.

Table 1. Memory Map

Bus	Addressing range	Size	Peripheral	Remarks
Flash	0x0000 0000 -0x0001 FFFF	128 KB	Main flash memory, system memory or SRAM, depending on BOOT configuration	
	0x0002 0000 -0x07FF FFFF	~ 128 MB	Reserved	
	0x0800 0000 -0x0801 FFFF	128 KB	Main Flash memory	

Bus	Addressing range	Size	Peripheral	Remarks
Flash	0x0802 0000 -0x1FFD FFFF	~ 256 MB	Reserved	
	0x1FFE 0000 -0x1FFE 01FF	0.5 KB	Reserved	
	0x1FFE 0200 -0x1FFE 0FFF	3 KB	Reserved	
	0x1FFE 1000 -0x1FFE 1BFF	3 KB	Reserved

1.3 Embedded SRAM

It features up to 8K bytes of static SRAM.

It can be accessed as bytes, half-words (16 bits) or full words (32 bits). The SRAM start address is 0x2000 0000.

- SRAM up to 8K bytes on the data bus.

1.4 Overview of FLASH memory

The flash memory includes two different storage areas:

- The main block includes the program data area and the user data area (if necessary)
- The information block includes four parts:
  - Option bytes - Containing hardware and user storage protection configuration options.
  - System memory - Containing boot loader code. See Section ”Embedded Flash Memory”.

The flash memory interface, based on AHB protocol, executes instructions and accesses data. With the prefetch buffer function, it accelerates the code execution speed of CPU.

1.5 Boot configuration

3 different boot modes can be selected through BOOT0 pins and nBOOT1 bit, as shown in the following table.

Table 2. Boot Modes

Boot mode selection		Boot mode	Aliasing
nBOOT1 bit	BOOT0 pin		
x	0	Main flash memory	Main flash memory is selected as boot space
1	1	System memory	System memory is selected as boot space
0	1	Embedded SRAM	Embedded SRAM is selected as boot space

The values on the BOOT pins are latched on the 4th rising edge of SYSCLK after a reset. It is up to the user to set the BOOT1 and BOOT0 pins after Reset to select the required boot mode.

The BOOT pins are also re-sampled when waking up from Standby mode. Consequently, they must be kept in the required Boot mode configuration in Standby mode.

After this startup delay has elapsed, the CPU fetches the top-of-stack value from address 0x00000000, then starts code execution from the boot memory starting from 0x00000004. Depending on the selected boot mode, main Flash memory, system memory or SRAM is accessible as follows:

- Boot from main Flash memory: the main Flash memory is aliased in the boot memory space (0x0000 0000), but still accessible from its original memory space (0x0800 0000). In other words, the Flash memory contents can be accessed starting from address 0x0000 0000 or 0x0800 0000.
- Boot from system memory: the system memory is aliased in the boot memory space (0x0000 0000), but still accessible from its original memory space (0x1FFF F400).
- Boot from the embedded SRAM: SRAM is aliased in the boot memory space (0x0000 0000), but still accessible from its original memory space (0x2000 0000).

Embedded boot loader

The embedded boot loader is located in the System memory, programmed by the manufacturer during production. It is used to reprogram the Flash memory with UART1.

2 Embedded flash(FLASH)

Embedded flash(FLASH)

2.1 Main features

- Up to 64K bytes of flash memory

The flash memory interface features:

- Data interface with prefetch buffer (2x64-bit)
- Option byte Loader
- Flash program/erase operation
- Read / write protection
- Low power mode

2.2 Functional description

2.2.1 Structure

The flash space consists of 64-bit memory cells, in which both code and data can be saved. The main block is divided into 128 pages (1 K bytes per page) or 32 sectors (4 K bytes per sector), and the write protection is set in sectors (see related content of ”Storage Protection”).

Table 3. Flash Module Structure

Module	Name	Address	Size(bytes)
Main memory	Page 0	0x0800 0000 - 0x0800 03FF	1K
	Page 1	0x0800 0400 - 0x0800 07FF	1K
	Page 2	0x0800 0800 - 0x0800 0BFF	1K
	Page 3	0x0800 0C00 - 0x0800 0FFF	1K

	System memory	0x1FFF F400 - 0x1FFF F7FF	1K
	Option bytes	0x1FFF F800 - 0x1FFF F80F	16
Flash memory interface registers	FLASH_ACR	0x4002 2000 - 0x4002 2003	4
	FLASH_KEYR	0x4002 2004 - 0x4002 2007	4
	FLASH_OPTKEYR	0x4002 2008 - 0x4002 200B	4
	FLASH_SR	0x4002 200C - 0x4002 200F	4
	FLASH_CR	0x4002 2010 - 0x4002 2013	4
	FLASH_AR	0x4002 2014 - 0x4002 2017	4
	Reserved	0x4002 2018 - 0x4002 201B	4
	FLASH_OBR	0x4002 201C - 0x4002 201F	4
	FLASH_WRPR	0x4002 2020 - 0x4002 2023	4

2.2.2 Reading flash

Embedded flash modules, like common storage space, can be directly addressed and accessed. The operation of reading flash module shall undergo a special judgment process.

Both instruction fetch and data fetch are performed through AHB bus and can be executed in the manner specified by the option in the flash access control register (FLASH_ACR):

- Instruction fetch: CPU running speed can be increased after the prefetch buffer is enabled
- Latency: number of wait states for a correct read operation

Instruction fetch

Instructions are fetched by CPU through AHB. With the prefetch module, the instruction fetch efficiency is improved.

Prefetch buffer

Prefetch buffer (2x64-bit): It is automatically opened after reset. Since the size of each buffer (64-bit) is the same as the bandwidth of the flash, the contents of the entire buffer can be updated only by reading flash memory once. Due to the existence of the prefetch buffer, the CPU can run at a higher dominant frequency. In each time, the CPU fetches a word up to 32 bits; the next instruction is waiting in the buffer while one instruction is being fetched.

Prefetch controller

The prefetch controller will timely access the flash according to the available space in the prefetch buffer. In case of at least one available space in the prefetch buffer, the prefetch controller will initiate a read request. After reset, the prefetch buffer is opened by default, and can only be enabled/disabled if SYSCLK is lower than 24 MHz and the AHB clock

has not undergone any frequency division (SYSCLK must be equal to HCLK). Usually, prefetch buffer has already determines its on/off state during the initialization process. At this time, MCU is running under the 8 MHz oscillator.

Note: When the prescaler of AHB clock is not equal to 1, the prefetch buffer shall initiate the access latency.

Access latency

In order to ensure the correct flash reading, the speed ratio of prefetch controller shall be specified in LATENCY 2: 0 in the flash access control register, and it is equal to the number of latent periods to be inserted between each flash accessing to the next access. After reset, this value defaults to zero, namely, there is no latent period to be inserted.

2.2.3 Programming and erasing flash

The embedded flash supports online programming and in-application programming.

ICP refers to rewriting flash online through SWD and burning the user code into the MCU. ICP provides a simple and efficient method, not requiring chip clamping during its writing.

Unlike ICP, IAP (in-application programming) enables downloading programs or data through any communication interface (I/Os, USB, UART, I2C, SPI, etc.) supported by MCU. IAP allows users to rewrite applications while running them, provided that some applications must be burned in advance by ICP/ISP.

The burn-in and erase operations can be completed within the whole operating voltage range of the product, and they are achieved with the following 7 registers:

- Key register (FLASH_KEYR)
- Option-byte key register (FLASH_OPRKEYR)
- Flash control register (FLASH_CR)
- Flash status register (FLASH_SR)
- Flash address register (FLASH_AR)
- Option byte register (FLASH_OBR)
- Write protection register (FLASH_WRPR)

As long as the CPU does not access the Flash space, the ongoing Flash programming will not hinder the operation of the CPU. That is to say, in the process of programming/erasing Flash, any access to Flash will disable the bus and it will not resume until the programming/erasing operation is completed, which means that instruction fetch and data access cannot be performed in case of Flash programming/erasing.

In the process of programming/erasing Flash space, the internal oscillator (HSI) must be on.

Unlocking Flash space

After reset, Flash memory is protected by default, preventing accidental erasing. The FLASH_CR is not allowed to be rewritten and the access to the FLASH_CR will not be authorized unless a series of unlocking operations for the FLASH_KEYR are performed. These operations include the following 2 write operations:

- Write key 1 = 0x45670123
- Write key 2 = 0xCDEF89AB

Any wrong sequence will lock FLASH_CR until the next reset.

In case of invalid keyword, a bus error will cause a hardware error interrupt; in case of KEY1 error, it will immediately interrupt, while a correct KEY1 will also lead to an interrupt when KEY2 error occurs.

Main flash programming

The 16-bit main flash can be programmed at a time. When PG bit in FLASH_CR is 1, writing a half words (16 bits) corresponding to the address is a programming operation. If you try to write another length instead of half words, the operation will cause a hardware error interrupt.

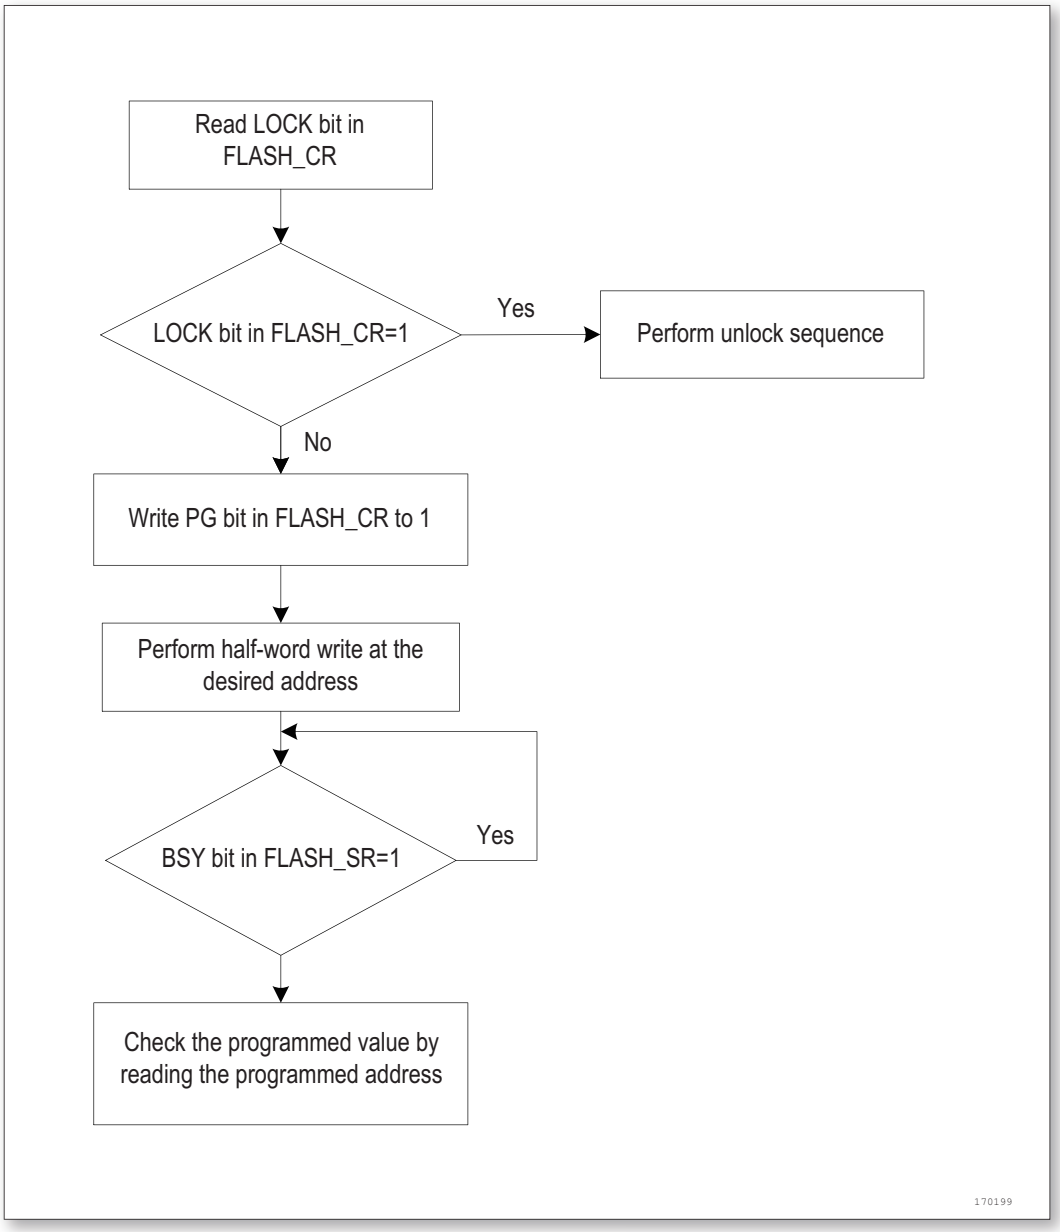

Figure 2. Programming Flow

The Flash memory interface will pre-read and judge whether the bytes behind those to be programmed are all 1s. If not, the programming operation will be automatically cancelled and an error warning will be prompted on the PGERR bit of the FLASH_SR.

If the write protection bit in FLASH_WRPR, corresponding to the address to be programmed, is valid, the programming will be disabled, and an error warning will be also generated. In addition, a prompt will be given at the EOP bit in FLASH_SR after the programming.

The programming process in the standard mode of the main Flash memory is as follows:

- Check BSY bit in FLASH_SR, to confirm that the previous operation has ended
- Set PG bit in FLASH_CR
- Write data to the target address in half words
- Wait for BSY in FLASH_SR to return to zero
- Read data for validation

Note: these registers cannot be written when the BSY bit in FLASH_SR is 1.

Erasing Flash memory

Flash memory can be erased by pages or whole pieces.

Page erasing

The specific procedures are as follows:

- Check BSY bit in FLASH_SR, to confirm that the previous operation has ended
- Set the PER bit in the FLASH_CR to 1
- Write the FLASH_AR, to select the page to be erased
- Set the STRT bit in the FLASH_CR to 1
- Wait for BSY in FLASH_SR to return to zero
- Read the erased pages for validation

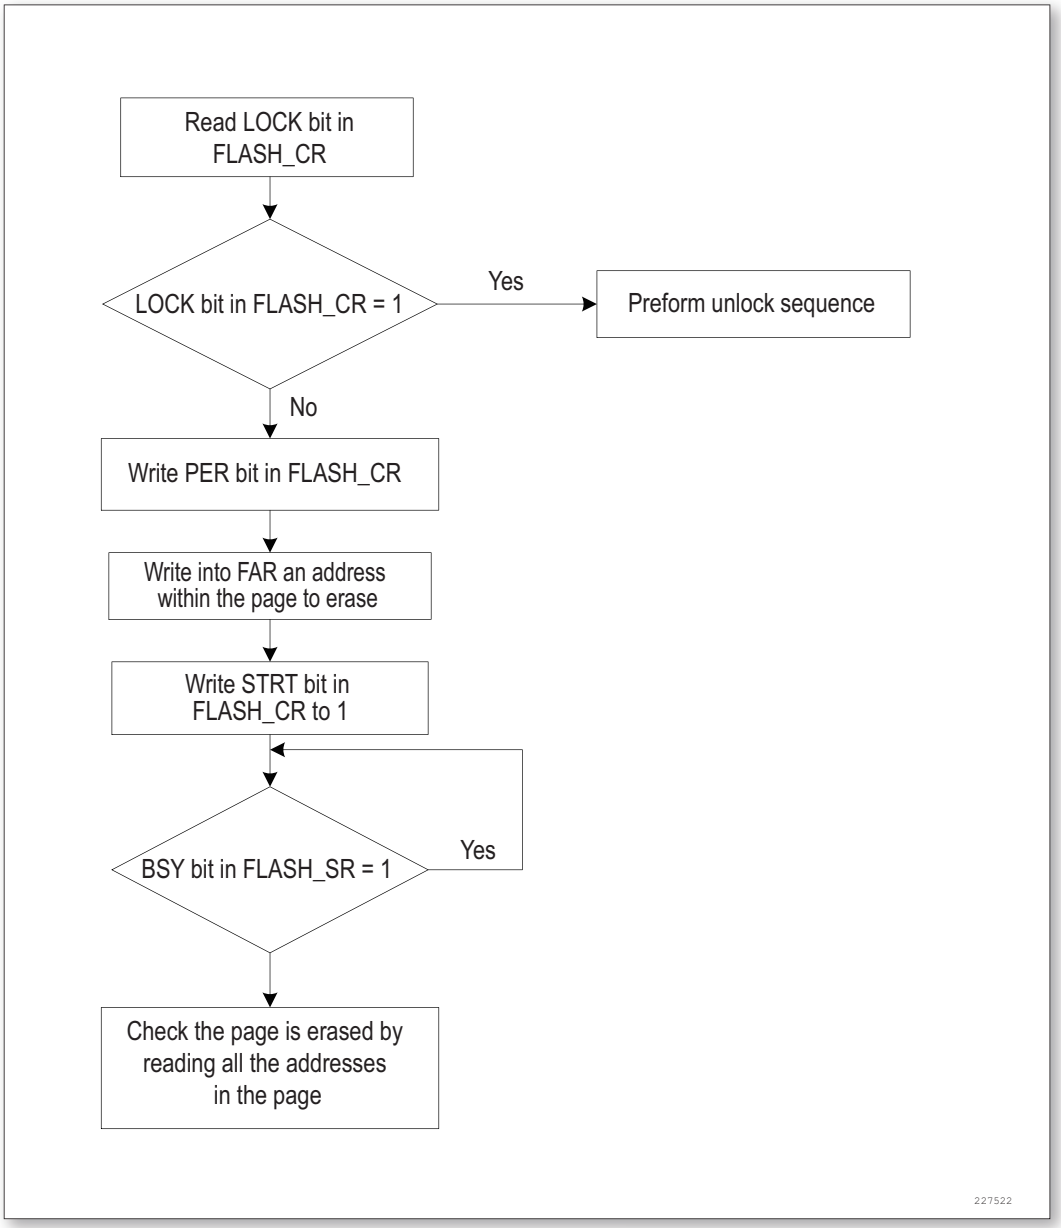

Figure 3. Page Erasing Process of Flash Register

Whole erasing

The entire Flash user area can be erased at one time by using the whole erasing command, and the information block will not be affected by this command. The specific steps are as follows:

- Check BSY bit in FLASH_SR, to confirm that the previous operation has ended
- Set the MER bit in the FLASH_CR to 1
- Set the STRT bit in the FLASH_CR to 1
- Wait for BSY bit to return to zero
- Read and validate all pages

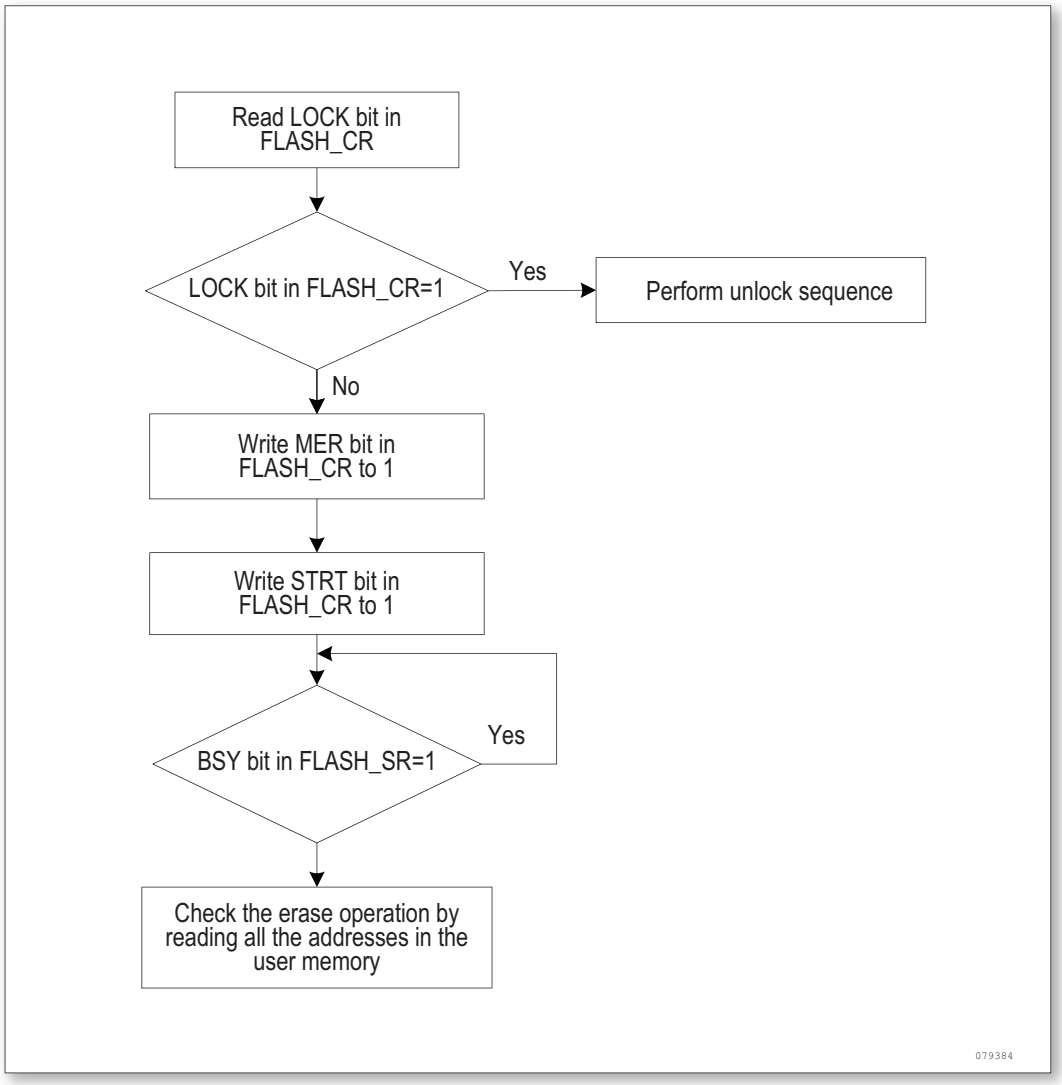

Figure 4. Whole Erasing Process of Flash Register

Option bytes programming

The programming of option bytes is different from that for the conventional user address, including 2 write protections and 1 hardware configuration. After the Flash access restriction is lifted, the FLASH_OPTKEYR needs to be written with keywords. After that, the OPTWRE bit in the FLASH_CR will be set to '1', then the OPTPG bit in the FLASH_CR can be set first, and then the target address can be written in half words. Similarly, it will automatically check if the option byte is 1. If not, the relevant operation will be cancelled and an error will be prompted at the WRPRTERR bit in FLASH_SR. After the programming, a prompt will be given at the EOP bit of FLASH_SR.

The option byte is 16-bit data, the valid data is the lower-8-bit, and the upper 8 bits are the inverse of the lower 8 bits. In the programming process, the hardware will automatically set the upper 8 bits to the inverse code of the lower 8 bits, to ensure that the write value of the option byte is always correct. The steps are as follows:

- Check BSY bit in FLASH_SR, to confirm that the previous operation has ended
- Unlock OPTWRE bit in FLASH_CR

- Set the OPTPG bit in the FLASH_CR to 1
- Write data (half word) to the target address
- Wait for BSY bit to return to zero
- Read and validate that a whole erasing will be automatically triggered when the protection option byte is changed from the protected state to the unprotected state. If the user only wants to rewrite other bytes, the whole erasing will not be activated. This mechanism is used to protect the Flash.

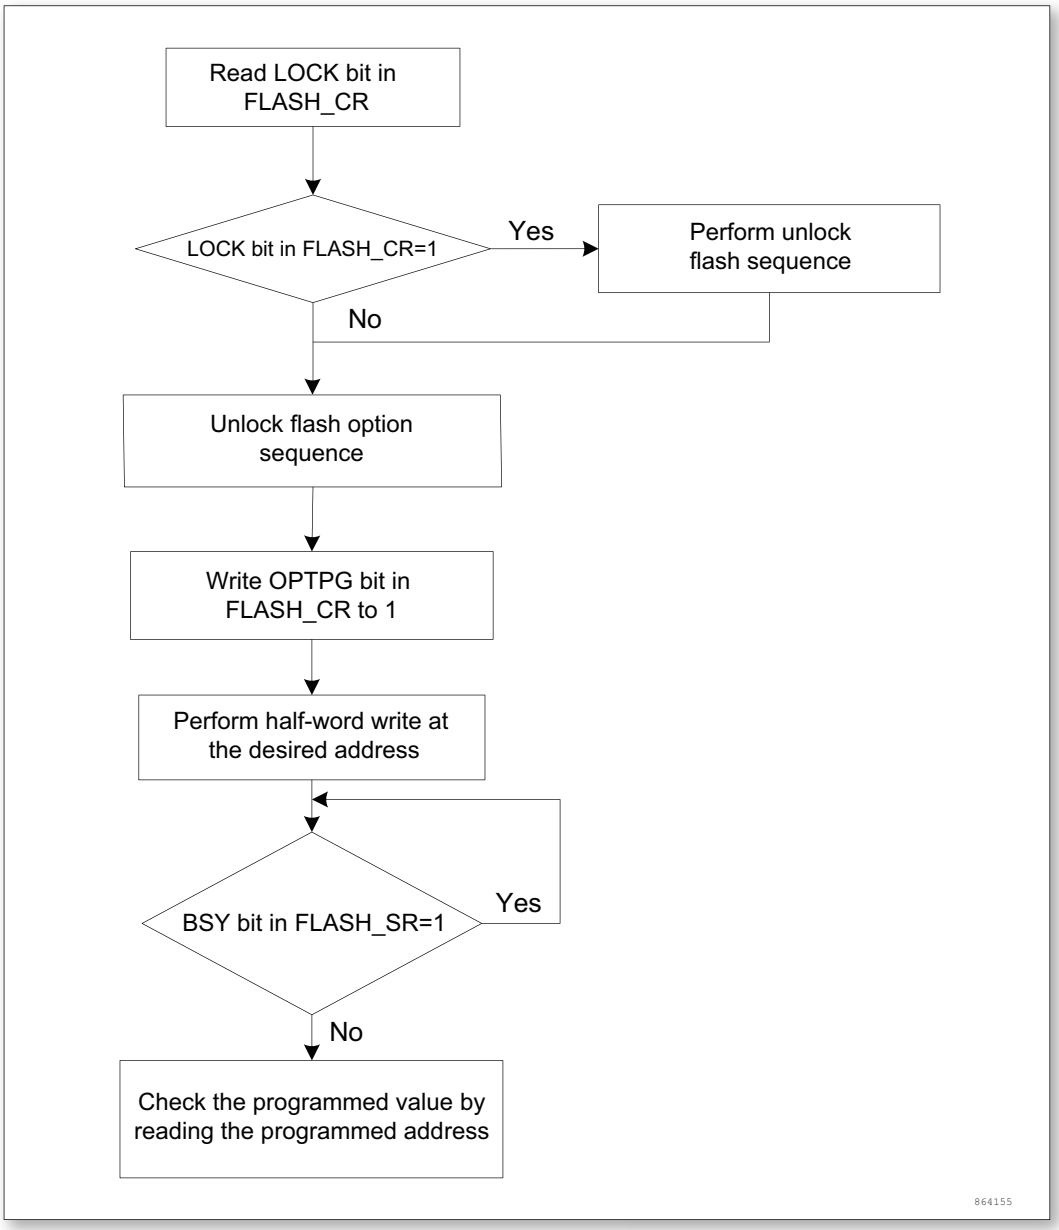

Figure 5. Option Byte Programming Process

Erasing process

The erasing process of option bytes is as follows:

- Check BSY bit in FLASH_SR, to confirm that the previous operation has ended
- Unlock OPTWRE bit in FLASH_CR

- Set OPTER bit in FLASH_CR to 1
- Set the STRT bit in the FLASH_CR to 1
- Wait for BSY bit to return to zero
- Read and validate

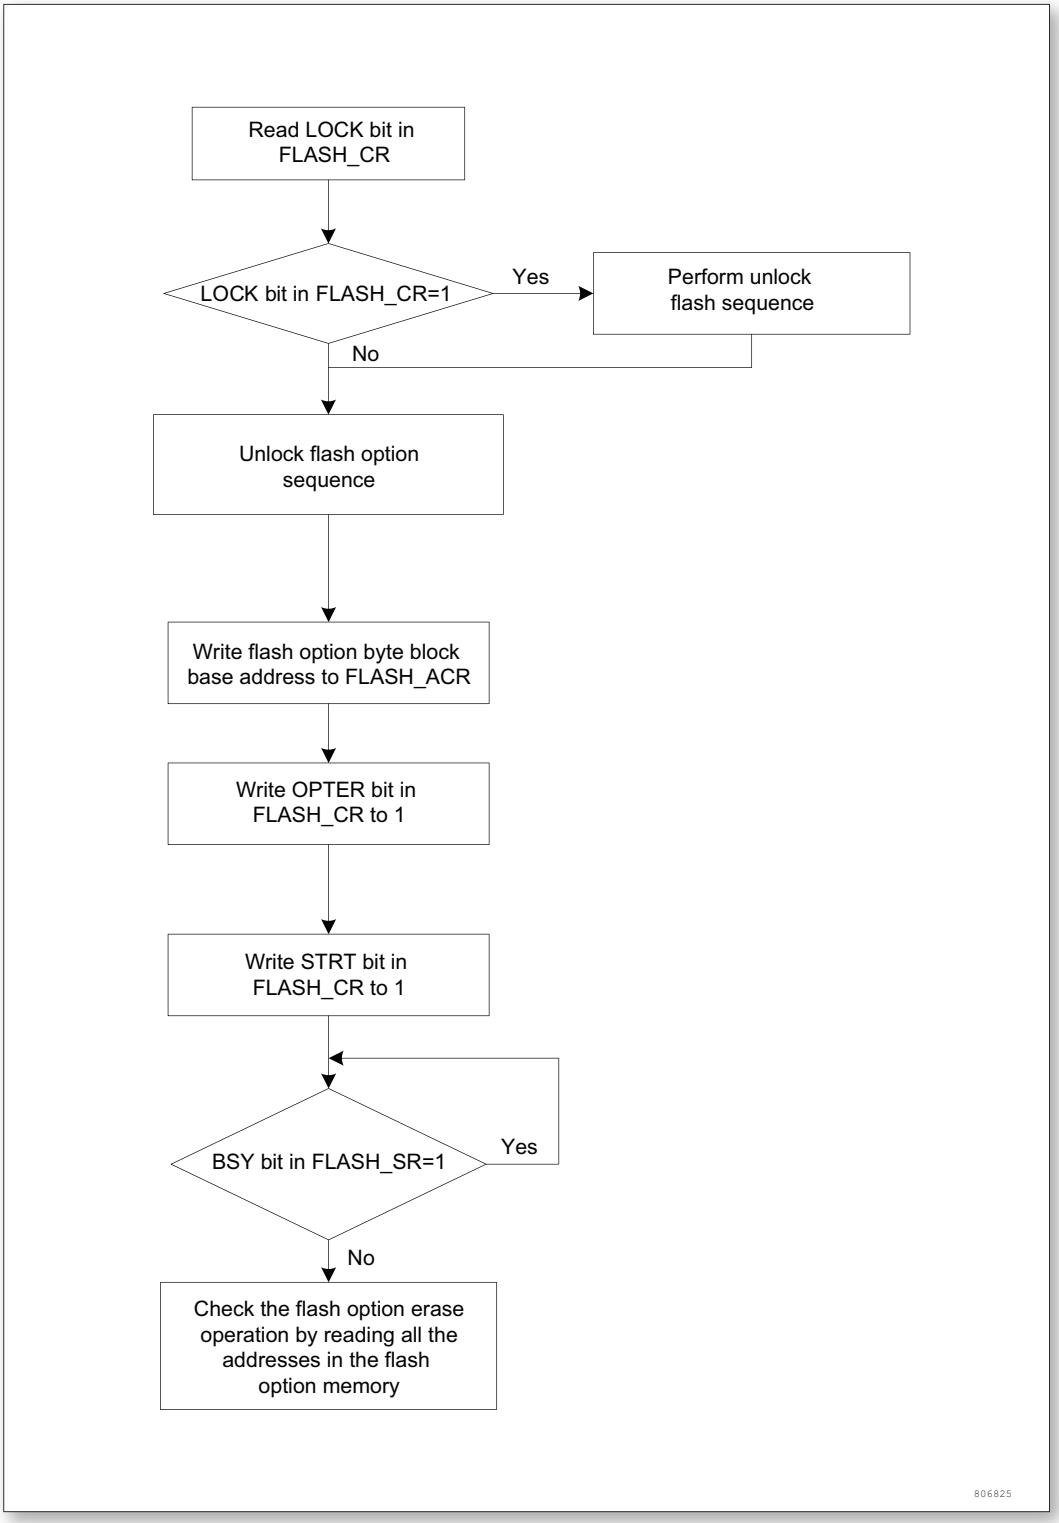

Figure 6. Option Byte Erasing Process

2.3 Storage protection

It is used to prevent the codes in the Flash area of the user area from being read by untrusted codes, and to prevent accidental erasure of the Flash in case of running-out. The minimum unit of write protection is one sector (4 pages).

2.3.1 Write protection of main space

The write protection is controlled by one sector (4 pages), to configure the WRP bit in the option byte, and the subsequent system reset will load the new option byte, to enable the protection. If an attempt is made to write or erase a protected sector, the WRPRTERR flag bit in FLASH_SR will be set.

Unclocking

It is applicable to the startup program realized and programmed by the user:

- Erase the entire option byte area by using the OPTER bit of the flash control register (FLASH_CR);
- Reset the system and reload option bytes (including new WRP bytes), to unlock the write protection.

With this method, unlock the write protection of the entire main flash module, excepting Pages 0-3 which are still protected.

2.3.2 Write protection of option bytes

By default, the option byte block is always readable and write protected. To write (programming/erasing) an option byte block, write the correct key sequence in the OPTKEYR (the same as the locking operation), then enable the write operation to the option byte block. Note that the OPTWRE bit in the FLASH_CR indicates the write permission, and disable the write operation by clearing this bit.

2.4 Flash interrupt

Table 4. Flash Interrupt Request

Interrupt event	Event flag	Enable control bit
End of operation	EOP	EOPIE
Write protection error	WRPRTERR	ERRIE
Programming error	PGERR	ERRIE

2.5 Description of option bytes

Option bytes are configured by the user according to the application requirements, for example, a hardware-based watchdog or a software-based watchdog can be selected.

Each 32-bit word in the option byte is classified into the following formats:

Table 5. Option Byte Format

Bits 31 ~ 24	Bits 23 ~ 16	Bits 15 ~ 8	Bits 7 ~ 0
Inversion of option byte 1	Option byte 1	Inversion of option byte 0	Option byte 0

Note: The inversed code is automatically achieved by hardware, and cannot be written through the software.

The organization of option bytes in the option byte block is as shown in the following table.

Option bytes can be read from the memory addresses listed in the following table or from the option byte register (FLASH_OBR).

Note: The newly-written option byte (user's or read/write-protected) will not take effect until the system is reset.

Table 6. Structure of Option Bytes

Address	[31: 24]	[23: 16]	[15: 8]	[7: 0]
0x1FFF F800	nUSER	USER		
0x1FFF F804	nData1	Data1	nData0	Data0
0x1FFF F808	nWRP1	WRP1	nWRP0	WRP0
0x1FFF F80C	nWRP3	WRP3	nWRP2	WRP2

Table 7. Description of Option Bytes

Memory address	Option bytes
0x1FFF F800	Bit[31: 24] nUSER Bit[23: 16] USER: user option byte (saved in FLASH_OBR[9: 2]). It is used to configure the following functions: Select watchdog event: hardware or software Note: Only use Bits [20] and [18: 16], and do not use Bits [23: 21] and [19]. Bit 20: nBOOT1 Bit 18: nRST_STDBY 0: Reset when entering standby mode 1: Do no reset when entering standby mode Bit 17: nRST_STOP 0: Reset when entering STOP mode 1: Do not reset when entering STOP mode Bit 16: WDG_SW 0: Hardware watchdog 1: Software watchdog

Memory address	Option bytes
0x1FFF F804	Datax: 2-byte user data This address can be programmed through the programming methods for option bytes. Bits [31: 24]: nData1 Bits [23: 16]: Data1(saved in FLASH_OBR[25: 18]) Bits [15: 8]: nData0 Bits [7: 0]: Data0 (saved in FLASH_OBR[17: 10])
0x1FFF F808	WRPx: Flash write protection for option bytes Bits [31: 24]: nWRP1 Bits [23: 16]: WRP1(saved in FLASH_WRPR[15: 8]) Bits [15: 8]: nWRP0 Bits [7: 0]: WRP0(saved in FLASH_WRPR[7: 0])
0x1FFF F80C	WRPx: Flash write protection for option bytes Bits [31: 24]: nWRP3 Bits [23: 16]: WRP3(saved in FLASH_WRPR[31: 24]) Bits [15: 8]: nWRP2 Bits [7: 0]: WRP2(saved in FLASH_WRPR[23: 16]) Each bit in the option byte WRPx is used to protect 4 memory pages in the main memory: 0: Write protection is enabled 1: Write protection is disabled Four user option bytes are used to protect the main memory of 128 K bytes. WRP0: write protection on Pages 0 ~ 31 WRP1: write protection on Pages 32 ~ 63 WRP2: write protection on Pages 64 ~ 95 WRP3: write protection on Pages 96 ~ 127

After each system reset, the option byte loader (OBL) reads the data of the information block and saves it in the option byte register (FLASH-OBR); each select bit has its inverse code bit in the information block. When the select bit is loaded, the inverse code bit is used to validate whether the select bit is correct. In case of any difference, an option byte error flag (OPTERR) will be generated. When an option byte error occurs, the corresponding option byte is set to 0xFF. When the option byte and its inverse code are 0xFF (erased state), the above verification function is disabled.

All the select bits (excluding their inversed code bits) are used to configure the microcontroller, and the option byte register is read by CPU.

2.6 Description of Flash register

Table 8. Overview of Flash Register

Offset	Acronym	Register Name	Reset	Section
0x00	FLASH_ACR	Flash access control register	0x00000018	section 2.6.1
0x04	FLASH_KEYR	FPEC key register	0xXXXXXXXX	section 2.6.2

OPTKEYR															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bit	Field	Type	Reset	Description
31 : 0	OPTKEYR	w	0xXXXX XXXX	Option byte key These bits are used to enter the key of the option byte, to disable OPTWRE.

Note: All these bits are written only and 0 is returned when being read.

2.6.4 Flash status register(FLASH_SR)

Address offset: 0x0C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															

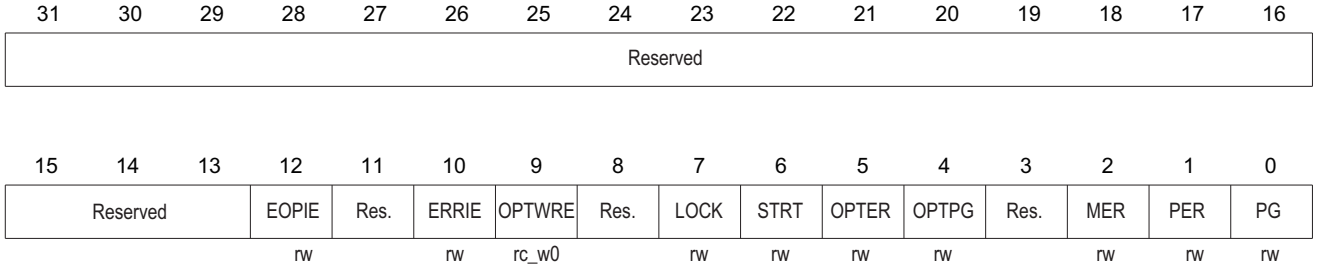
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved										EOP	WRPRTERR	Res.	PGERR	Res.	BSY
										rc_w1	rc_w1		rc_w1		r

Bit	Field	Type	Reset	Description
31 : 6	Reserved			Reserved, always read as 0.
5	EOP	rc_w1	0x00	End of operation When the flash operation (programming/erasing) is completed, the hardware sets this bit to '1', and eliminate this state by writing '1'. Note: EOP status will be set for every successful programming or erasing.
4	WRPRTERR	rc_w1	0x00	Write protection error When the flash address for write protection is programmed, the hardware sets this bit to '1', and eliminate this state by writing '1'.
3	Reserved			Reserved, always read as 0.
2	PGERR	rc_w1	0x00	Programming error Attempting to program an address that is not '0xFFFF', the hardware sets this bit to '1', and eliminate this state by writing '1'. Note: The STRT bit in the FLASH_CR shall be cleared before the programming.
1	Reserved			Reserved, always read as 0.
0	BSY	r	0x00	Busy This bit indicates that the flash operation is in progress. This bit is set to '1' when the flash operation begins and written to '0' at the end of operation or in case of an error.

2.6.5 Flash control register(FLASH_CR)

Address offset: 0x10

Reset value: 0x0000 0080



Bit	Field	Type	Reset	Description
31 : 13	Reserved			Reserved, always read as 0.
12	EOPIE	rw	0x00	End of operation interrupt enable This bit leads to an interrupt when the EOP bit in the FLASH_SR register changes to '1'. 0: Interrupt is disabled 1: Interrupt is enabled

Bit	Field	Type	Reset	Description
11	Reserved			Reserved, always read as 0.
10	ERRIE	rw	0x00	Error interrupt enable This bit enables an interrupt in case of an FPEC error (when PGERR/WRPRTERR in the Flash-SR is set to ’1’). 0: Interrupt is disabled 1: Interrupt is enabled
9	OPTWRE	rc_w0	0x00	Option byte write enable When this bit is ’1’, the option byte is allowed to be programmed. This bit is set to ’1’ when the correct key sequence is written in the FLASH_OPTKEYR. This bit can be cleared by writing 0 through the software.
8	Reserved			Reserved, always read as 0.
7	LOCK	rw	0x01	Lock Only ’1’ can be written. When this bit is ’1’, FPEC and FLASH_CR are locked. After detecting the correct unlocking sequence, the hardware automatically clears and sets this bit to ’0’. After an unsuccessful unlock operation, this bit cannot be changed again until the next system reset.
6	STRT	rw	0x00	Start When this bit is ’1’, an erasing operation will be enabled. This bit can only be set to ’1’ by software and cleared automatically when BSY changes to ’1’.
5	OPTER	rw	0x00	Option byte erase Option bytes are erased.
4	OPTPG	rw	0x00	Option byte programming Option bytes are programmed
3	Reserved			Reserved, always read as 0.
2	MER	rw	0x00	Mass erase Select to erase all user pages.
1	PER	rw	0x00	Page erase Select to erase pages.
0	PG	rw	0x00	Programming Select to program.

2.6.6 Flash address register(FLASH_AR)

Address offset: 0x014

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FAR															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FAR															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bit	Field	Type	Reset	Description
31 : 0	FAR	w	0x0000 0000	Flash Address Select the address to be programmed before programming, and the page to be erased when erasing. Note: it is not allowed to write the register when the BSY bit in FLASH_SR is 1.

Change to current/last used address from hardware. During the page erasing, modify the register, to specify the page to be erased.

2.6.7 Option byte register(FLASH_OBR)

Address offset: 0x1C

Reset value: 0x03FF FC5C

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved						Data1								Data0	
						r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Data0						Reserved			nBOOT1	Res.	nRST_STDBY	nRST_STOP	WDG_SW	Res.	OPTERR
r	r	r	r	r	r				r		r	r	r		r

Bit	Field	Type	Reset	Description
31 : 26	Reserved			Reserved, always read as 0.
25 : 18	Data1	r	0xFF	Data1
17 : 10	Data0	r	0xFF	Data0
9 : 7	Reserved			Reserved, always read as 0.
6	nBOOT1	r	0x01	nBOOT1
5	Reserved			Reserved, always read as 0.
4	nRST_STDBY	r	0x01	Reset event when entering standby mode 0: Reset when entering standby mode 1: Do no reset when entering standby mode
3	nRST_STOP	r	0x01	Reset event when entering stop mode 0: Reset when entering STOP mode 1: Do not reset when entering STOP mode

Bit	Field	Type	Reset	Description
2	WDG_SW	r	0x01	Select watchdog event 0: Hardware watchdog 1: Software watchdog
1	Reserved			Reserved, always read as 0.
0	OPTERR	r	0x00	Option byte error When this bit is '1', it means that the option byte does not match its inverse code. Note: This bit is read-only.

The reset value of this register is related to the value written in the option byte, and the reset value of the OPTERR bit is related to the result of comparing the option byte with its inverse code when the option bytes are loaded.

2.6.8 Write protection register(FLASH_WRPR)

Address offset: 0x20

Reset value: 0xFFFF FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
WRP															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
WRP															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bit	Field	Type	Reset	Description
31 : 0	WRP	r	0xFFFF FFFF	Write protect This register contains write protection option bytes loaded by OBL. 0: The write protection is enabled 1: The write protection is disabled Note: These bits are read-only.

3 Power control (PWR)

Power control(PWR)

3.1 Power supply

The chip requires a 2.0-to-5.5 V operating voltage supply (V_{DD}). An embedded regulator is used to supply the internal 1.5 V power.

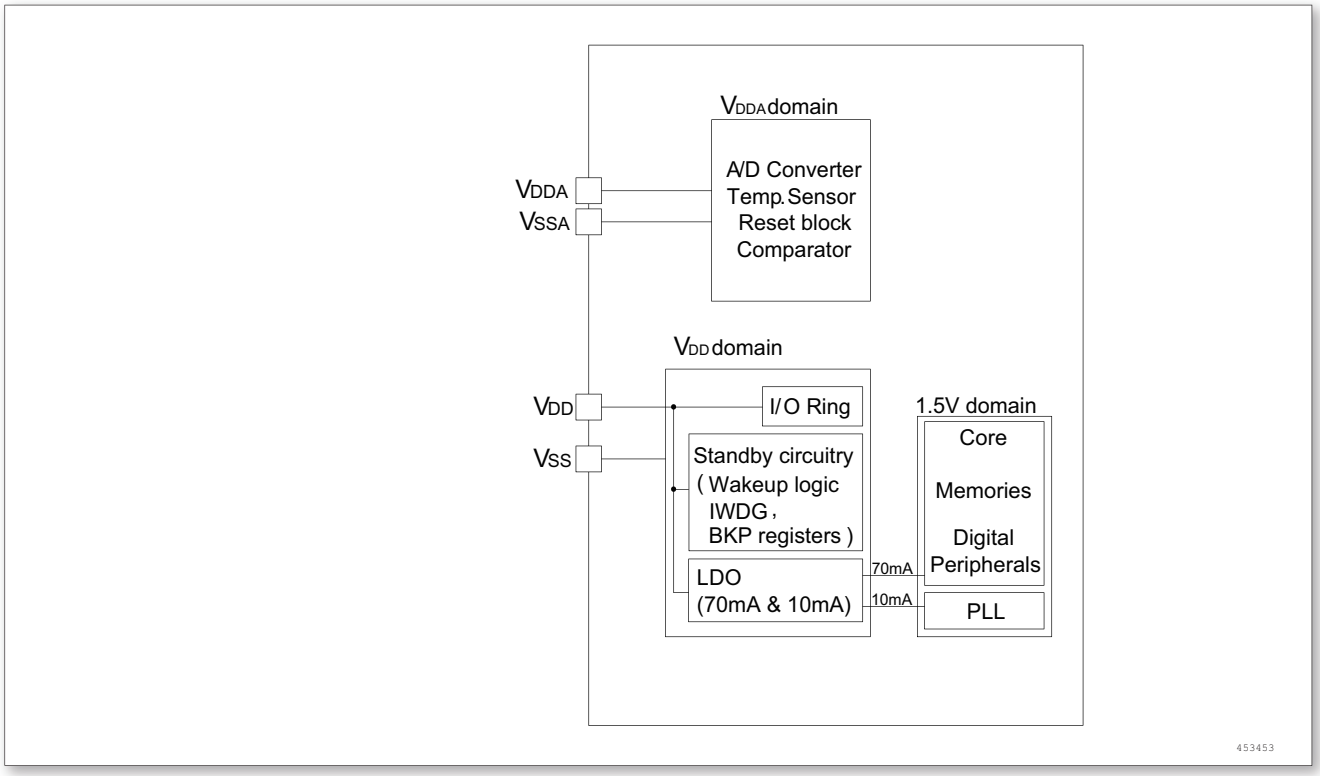


Figure 7. Power Supply Overview

Note: V_{DDA} and V_{SSA} must be connected to V_{DD} and V_{SS}.

3.1.1 Independent A/D converter supply and reference voltage

To improve conversion accuracy, the ADC has an independent power supply which can be separately filtered and shielded from noise on the PCB.

- The ADC supply input is available on a V_{DDA} pin
- An isolated supply ground connection is provided on pin V_{SSA}

When available (according to package), pin V_{REF-} must be tied to V_{SSA}.

3.1.2 Battery backup domain

The content of the Backup registers can be retained when 1.5 V voltage domain of the regulator is shut off.

3.1.3 Voltage regulator

The voltage regulator is always enabled after Reset. It works in three different modes depending on the application modes.

- In Run mode, the regulator supplies full power to the 1.5 V domain (core, memories and digital peripherals).
- In Stop mode, the regulator supplies low-power to the 1.5 V domain, preserving contents of registers and SRAM.
- In Standby Mode, the regulator is powered off. The contents of the registers and SRAM are lost except for the Standby circuitry and the Backup Domain.

3.2 Power supply supervisor

3.2.1 Power on reset (POR)/power down reset (PDR)

The device has an integrated POR/PDR circuitry that allows proper operation starting from/down to 1.5 V.

The device remains in Reset mode when V_{DD}/V_{DDA} is below a specified threshold, V_{POR}/V_{PDR}, without the need for an external reset circuit. For more details concerning the power on/power down reset threshold, refer to the electrical characteristics of the datasheet.

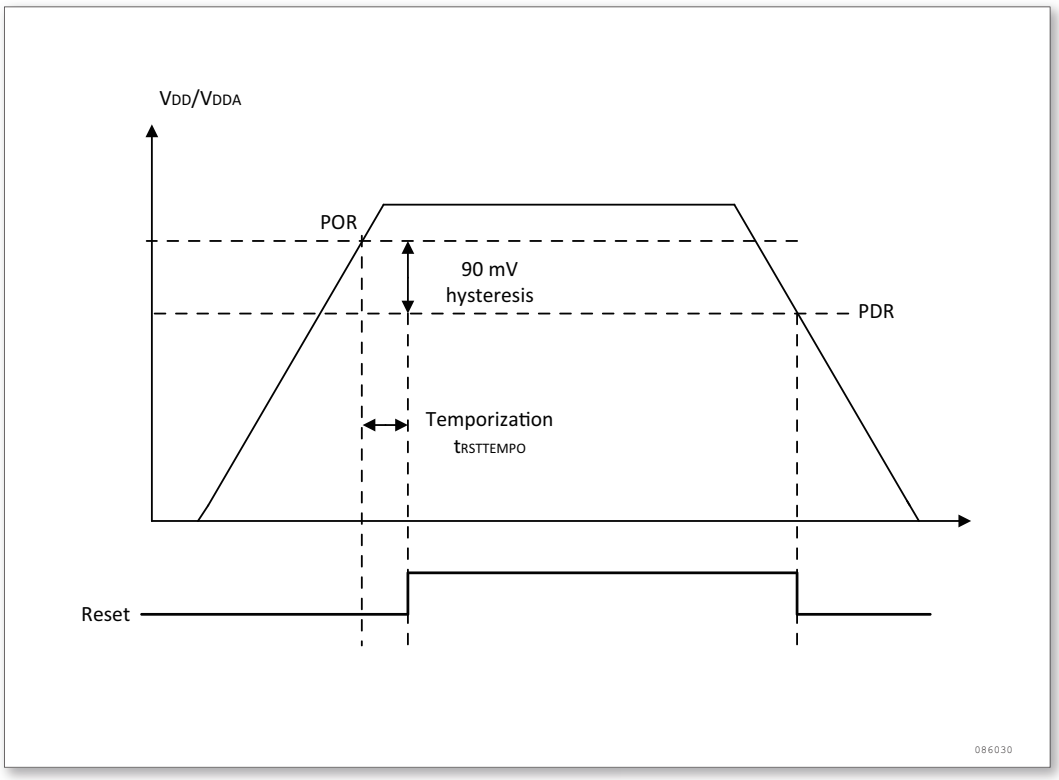

Figure 8. Power on Reset/Power Down Reset Waveform

3.2.2 Programmable voltage detector (PVD)

The PVD can be used to monitor the V_{DD} power supply by comparing it to a threshold selected by the PLS bits in the Power control register (PWR_CR).

The PVD is enabled by setting the PVDE bit.

A PVDO flag is available, in the Power control/status register (PWR_CSR), to indicate if VDD is higher or lower than the PVD threshold. This event is internally connected to the EXTI line16 and can generate an interrupt if enabled through the EXTI registers. The PVD output interrupt can be generated when VDD drops below the PVD threshold and/or when VDD rises above the PVD threshold depending on EXTI line16 rising/falling edge configuration. As an example, the service routine could perform emergency shutdown tasks.

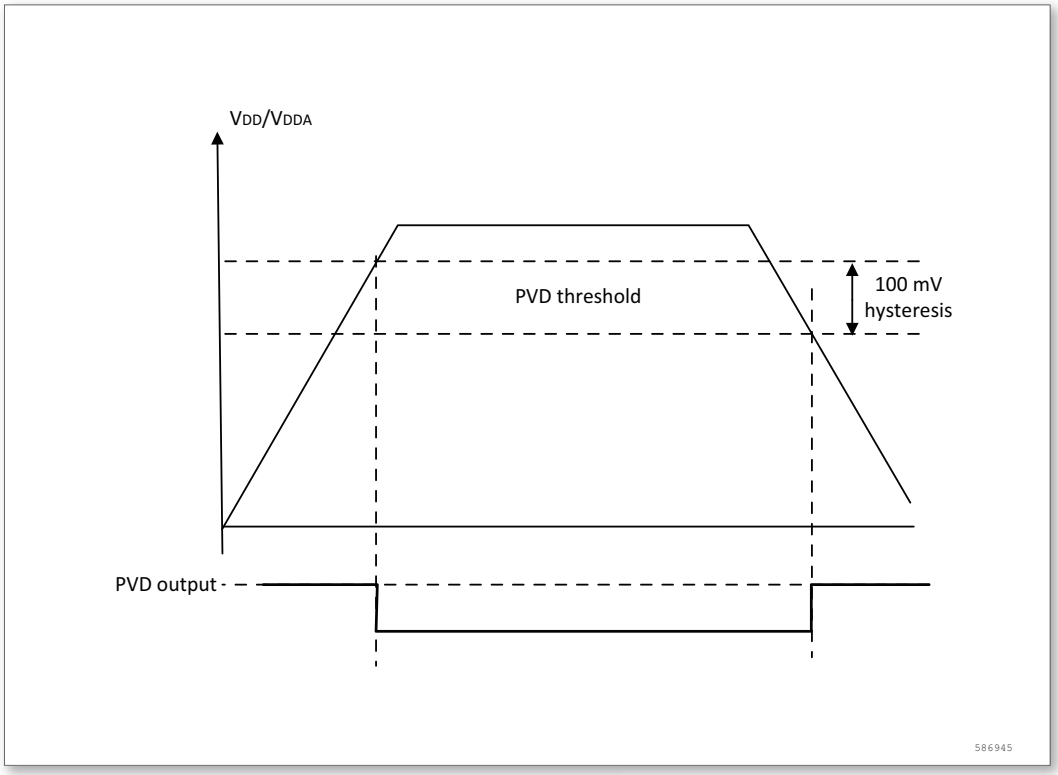

Figure 9. PVD Thresholds

3.3 Low-power modes

By default, the microcontroller is in Run mode after a system or a power Reset. Several low-power modes are available to save power when the CPU does not need to be kept running, for example, when waiting for an external event. It is up to the user to select the mode that gives the best compromise between low-power consumption, short startup time and available wakeup sources.

The device features three low-power modes:

- Sleep mode (CPU clock off, all peripherals including CPU peripherals like NVIC, SysTick, etc. are kept running)
- Stop mode (all clocks are stopped, and contents of register and SRAM are retained)

- Standby mode (1.5V domain is powered off, and the contents of the registers and SRAM are lost except for the Standby circuitry and the Backup Domain)

In addition, the power consumption in Run mode can be reduced by one of the following means:

- Slowing down the system clocks
- Gating the clocks to the APB and AHB peripherals when they are unused.

Table 9. Low-power Mode Summary

Mode	Entry	Wakeup	Effect on 1.5V domain clocks	Effect on V_{DD} domain clocks	Voltage regulator
Sleep (Sleep now or Sleep-on-exit)	WFI (Wait for Interrupt)	Any interrupt	CPU clock OFF, no effect on other clocks or ADC clock	None	ON
	WFE (Wait for Event)	Wakeup event			
Stop	PDDS bits + SLEEPDEEP bit + WFI or WFE	Any EXTI line (configured in the EXTI registers)	All 1.5V domain clocks OFF	PLL, HSI and HSE oscillators OFF	ON
Standby	PDDS bit + SLEEPDEEP bit + WFI or WFE	WKUP pin rising edge, external reset in NRST pin, and IWDG reset			OFF

3.3.1 Slowing down system clocks

In Run mode the speed of the system clocks (SYSCLK, HCLK, PCLK1, PCLK2) can be reduced by programming the prescaler registers. These prescalers can also be used to slow down peripherals before entering Sleep mode.

For more details refer to Section ”Clock Configuration Register (RCC_CFGR)

3.3.2 Peripheral clock gating

In Run mode, the HCLK and PCLKx for individual peripherals and memories can be stopped at any time to reduce power consumption.

To further reduce power consumption in Sleep mode the peripheral clocks can be disabled prior to executing the WFI or WFE instructions.

Peripheral clock gating is controlled by the AHB peripheral clock enable register (RCC_AHBENR), APB1 peripheral clock enable register (RCC_APB1ENR) and APB2 peripheral clock enable register (RCC_APB2ENR).

3.3.3 Sleep Mode

Entering Sleep mode

The Sleep mode is entered by executing the WFI (Wait For Interrupt) or WFE (Wait for Event) instructions. Two options are available to select the Sleep mode entry mechanism, depending on the SLEEPONEXIT bit in the system control register of CPU:

- Sleep-now: if the SLEEPONEXIT bit is cleared, the MCU enters Sleep mode as soon as WFI or WFE instruction is executed.
- Sleep-on-exit: if the SLEEPONEXIT bit is set, the MCU enters Sleep mode as soon as it exits the lowest priority ISR (interrupt service routine).

In the Sleep mode, all I/O pins keep the same state as in the Run mode.

Refer to Table 10 and Table 11 for details on how to enter Sleep mode.

Table 10. Sleep-now

Sleep-now mode	Description
Entry	WFI (Wait for Interrupt) or WFE (Wait for Event) while: - SLEEPDEEP = 0 - SLEEPONEXIT = 0 Refer to the CPU System Control register
Mode exit	If WFI was used for entry: Interrupt: Refer to Section ”Interrupt and Exception Vectors” If WFE was used for entry: Wakeup event: Refer to Section ”Wakeup Event Management”
Wakeup latency	None

Table 11. Sleep-on-exit

Sleep-on-exit mode	Description
Description	WFI (Wait for Interrupt) or WFE (Wait for Event) while: - SLEEPDEEP = 0 - SLEEPONEXIT = 1 Refer to the CPU System Control register
Mode exit	If WFE was used for entry:Interrupt or clear Bit 1 of CPU control register If WFE was used for entry: Wakeup event: Refer to Section ”Wakeup Event Management”
Wakeup latency	None

3.3.4 Stop mode

The Stop mode is based on the CPU deepsleep mode combined with peripheral clock gating. And the voltage regulator can be configured in normal mode.In Stop mode, all clocks in the 1.5 V domain are stopped, the PLL, the HSI and the HSE oscillators are disabled. SRAM and register contents are preserved.

In the Stop mode, all I/O pins keep the same state as in the Run mode.

Entering Stop mode

Refer to Table 12 for details on how to enter the Stop mode.

In Stop mode, the following features can be selected by programming individual control bits:

- Independent watchdog (IWDG): the IWDG is started by writing to its Key register or by hardware option.
- Internal oscillator (LSI): this is configured by the LSION bit in the Control/status register (RCC_CSR).

The ADC can also consume power in the Stop mode, unless they are disabled before entering it. To disable them, the ADON bit in the ADC_CR2 register shall be written to 0.

In addition, other GPIOs not used shall be configured with analog input, to prevent current consumption.

Exiting Stop mode

Refer to Table 12 for details on how to exit the Stop mode.

When exiting Stop mode by issuing an interrupt or a wakeup event, the HSI oscillator is selected as system clock, with the frequency of HSI frequency divided by 6.

When the voltage regulator operates in normal-power mode, an additional startup delay is incurred when waking up from Stop mode.

Table 12. Stop Mode

Stop Mode	Description
Entry	WFI (Wait for Interrupt) or WFE (Wait for Event) while: - Set SLEEPDEEP bit in CPU System Control register - Clear PDDS bit in Power Control register (PWR_CR) Note: To enter Stop mode, all EXTI Line pending bits (in Pending register (EXTI_PR)), all peripheral interrupt pending bits, and RTC Alarm flag must be reset. Otherwise, the Stop mode entry procedure is ignored and program execution continues.
must be reset	WFI (Wait for Interrupt) is executed in case of: Any EXTI Line configured in Interrupt mode (the corresponding EXTI Interrupt vector must be enabled in the NVIC). Refer to Section ”Interrupt and Exception Vectors”. If WFE (Wait for Event) is executed in case of: Any EXTI Line configured in event mode. Refer to Section ”Wakeup Event Management”.
Wakeup latency	HSI wakeup time

3.3.5 Standby mode

The Standby mode allows to achieve the lowest power consumption. It is based on the CPU deepsleep mode, with the voltage regulator disabled. The 1.5 V domain is consequently powered off. The PLL, the HSI oscillator and the HSE oscillator are also switched off. SRAM and register contents are lost except for registers in the Backup domain and Standby circuitry.

Entering Standby mode

Refer to Table 13 for details on how to enter the Standby mode.

In Standby mode, the following features can be selected by programming individual control bits:

- Independent watchdog (IWDG): the IWDG is started by writing to its Key register or by hardware option.
- Internal oscillator (LSI): this is configured by the LSION bit in the Control/status register (RCC_CSR).

Exiting Standby mode

The microcontroller exits the Standby mode when an external reset (NRST pin), an IWDG reset, a rising edge on the WKUP pin or the rising edge of an RTC alarm occurs. All registers are reset after wakeup from Standby except for Power control/status register (PWR_CSR).

After waking up from Standby mode, program execution restarts in the same way as after a Reset (boot pins sampling, vector reset is fetched, etc.). The SBF status flag in the Power control/status register (PWR_CSR) indicates that the core exits from the Standby mode.

Refer to Table 13 for details on how to exit the Standby mode.

Table 13. Standby Mode

Standby Mode	Description
Entry	WFI (Wait for Interrupt) or WFE (Wait for Event) while: - Set SLEEPDEEP bit in CPU System Control register - Set PDDS bit in Power Control register (PWR_CR) - Clear WUF bit in Power Control/Status register (PWR_CSR)
Exit	WKUP pin rising edge, external reset in NRST pin, and IWDG reset
Wakeup latency	Activating power regulator in the reset stage.

I/O states in Standby mode

In Standby mode, all I/O pins are high impedance except:

- Reset pin (still available)
- TAMPER pin if configured for tamper or calibration out
- WKUP pin, if enabled

Debug mode

By default, the debug connection is lost if the application puts the MCU in Stop or Standby mode while the debug features are used. This is due to the fact that the CPU core is no longer clocked.

However, by setting some configuration bits in the DBGMCU_CR register, the software can be debugged even when using the low-power modes extensively. For more details, refer to Section ”Debug Support for Low-power Modes”.

3.4 Power control registers

Table 14. Overview of Power Control Registers

Offset	Acronym	Register Name	Reset	Section
0x00	PWR_CR	Power control register	0x00000000	section 3.4.1
0x04	PWR_CSR	Power control/status register	0x00000000	section 3.4.2

3.4.1 Power control registers(PWR_CR)

Address offset: 0x00

Reset value: 0x0000 0000(reset by wakeup from Standby mode)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Field	Type	Reset	Description
31 : 9	Reserved			always read as 0.
8	EWUP	rw	0x00	Enable WKUP pin 1: WKUP pin is used for wakeup from Standby mode and forced in input pull down configuration (rising edge on WKUP pin wakes up the system from Standby mode). 0: WKUP pin is used for general purpose I/O. An event on the WKUP pin does not wakeup CPU from Standby mode. Note: This bit is reset by a system reset.
7:3	Reserved			always read as 0.
2	PVDO	rw	0x00	PVD output It is valid only if PVD is enabled by the PVDE bit. 1: V_{DD}/V_{DDA} is lower than the PVD threshold selected with the PLS bits. 0: V_{DD}/V_{DDA} is higher than the PVD threshold selected with the PLS bits. Note: The PVD is stopped by Standby mode. For this reason, this bit is equal to 0 after Standby or reset until the PVDE bit is set.
1	SBF	rw	0x00	Standby flag This bit is set by hardware and cleared only by a POR/PDR (power on reset/power down reset) or by setting the CSBF bit in the Power control register (PWR_CR). 1: System has been in Standby mode 0: System has not been in Standby mode

Bit	Field	Type	Reset	Description
0	WUF	rw	0x00	Wakeup flag This bit is set by hardware and cleared only by a POR/PDR (power on reset/power down reset) or by setting the CWUF bit in the Power control register (PWR_CR). 1: A wakeup event was received from the WKUP pin or from the RTC alarm 0: No wakeup event occurred Note: An additional wakeup event is detected if the WKUP pin is enabled (by setting the EWUP bit) when the WKUP pin level is already high.

4 Backup registers (BKP)

Backup registers (BKP)

4.1 BKP introduction

The backup registers are 10 16-bit registers for storing 20 bytes of user application data. They are implemented in the backup domain that remains powered on by V_{DD} when the 1.5 V power is switched off. They are not reset when the system wakes up from Standby mode or by a system reset or power reset.

After reset, access to the Backup registers and RTC is disabled and the Backup domain (BKP) is protected against possible parasitic write access.

To enable access to the Backup registers proceed as follows:

- Enable the power and backup interface clocks by setting the PWREN bits in the RCC_APB1ENR register.

4.2 BKP main features

- 20-byte backup data registers.

4.3 BKP description

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

Table 15. Overview of BKP Registers

Offset	Acronym	Register Name	Reset	Section
0x10 + 4 × (n - 1)	BKP_DRn	Backup data register x	0x00000000	section 4.3.1

4.3.1 Backup data register n(BKP_DRn)(n = 1...10)

Address offset: 0x10 + 4 × (backup data register number - 1)

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BKP															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit	Field	Type	Reset	Description
15 : 0	BKP	rw	0x0000	BKP: backup data These bits can be used to write user data. Note: The BKP_DRn registers are not reset by a System reset or Power reset or when the system wakes up from Standby mode. They are reset by a Backup Domain reset or by a TAMPER pin event (if the TAMPER pin function is activated).

5 Reset and clock control (RCC)

Reset and clock control (RCC)

5.1 Reset

There are two types of reset, defined as system reset and power reset.

5.1.1 System reset

A system reset sets all registers to their reset values except the reset flags in the clock controller CSR register, standby and wakeup flags in power control register (CSR) and the registers in the Backup domain.

A system reset is generated when one of the following events occurs:

1. A low level on the NRST pin (external reset)
2. Window watchdog end of count condition (WWDG reset)
3. Independent watchdog end of count condition (IWDG reset
4. A software reset (SW reset)

The reset source can be identified by checking the reset flags in the Control/Status register (RCC_CSR).

Software reset

The SYSRESETREQ bit in CPU Application Interrupt and Reset Control Register must be Set to ”1” to force a software reset.

5.1.2 Power reset

A power reset is generated when one of the following events occurs:

1. Power-on/power-down reset (POR/PDR reset)
2. When exiting Standby mode

A power reset sets all registers to their reset values except the Backup domain.

These sources in Figure 10 act on the NRST pin and it is always kept low during Reset. The RESET service routine vector is fixed at address 0x0000_0004.

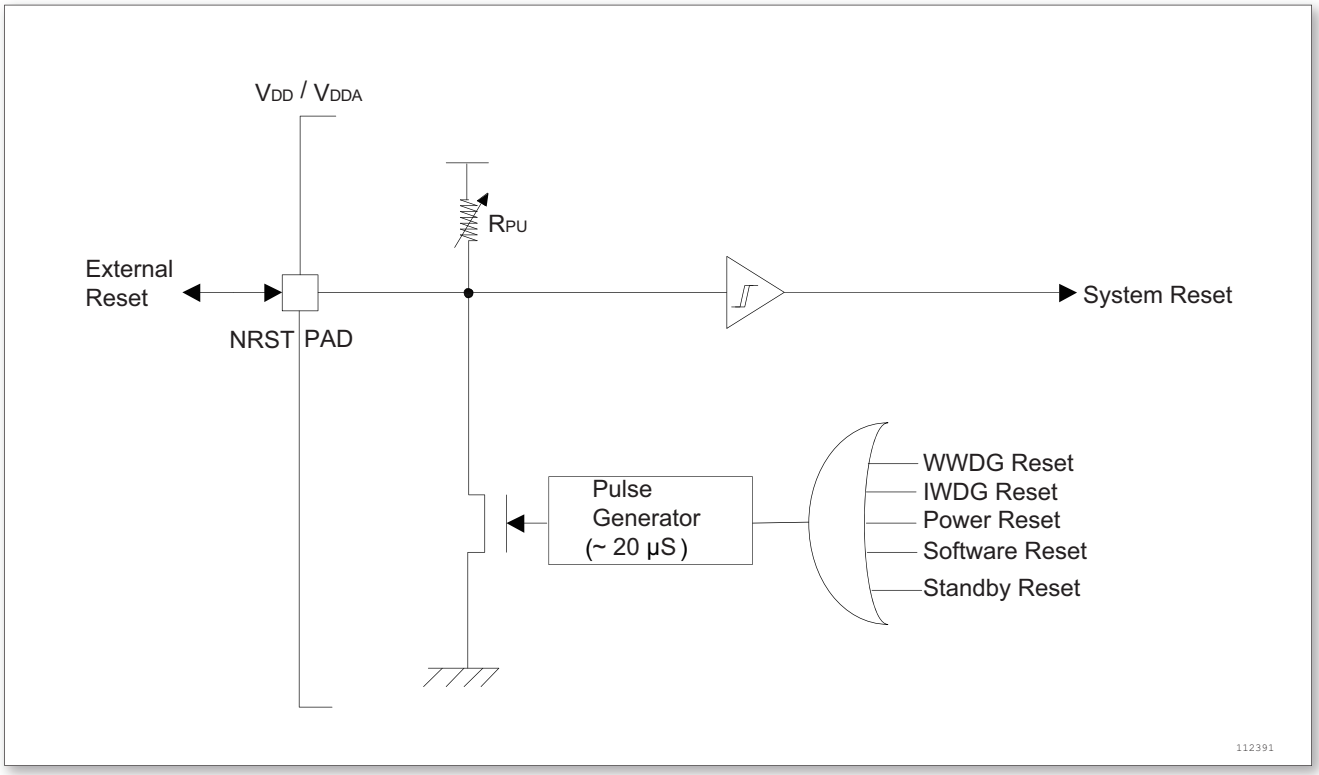

Figure 10. Reset Circuit

5.2 Clocks

Four different clock sources can be used to drive the system clock (SYSCLK):

- HSI oscillator clock
- HSE oscillator clock
- PLL clock
- LSI clock

Each clock source can be switched on or off independently when it is not used, to optimize power consumption.

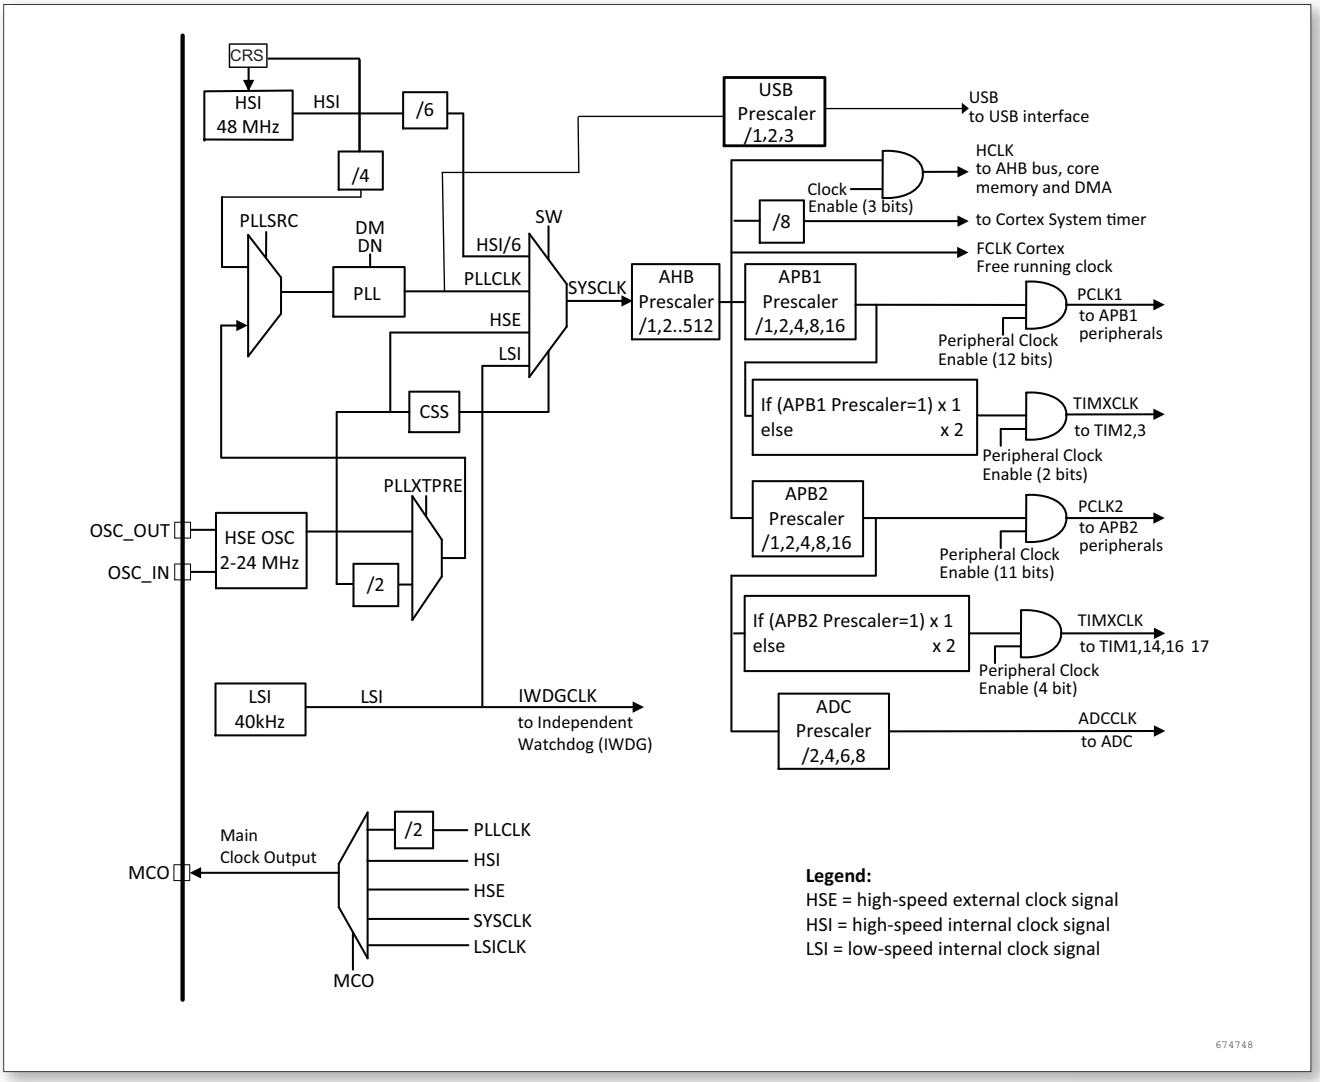

Figure 11. Clock Tree

Several prescaler factors allow the configuration of the frequency of AHB, the high-speed APB (APB2) and the low-speed APB (APB1) domains. The maximum frequency of the AHB, APB1 and the APB2 domains is 48MHzMHz.

The RCC feeds the CPU System Timer (SysTick) external clock with the AHB clock divided by 8. This clock can be used or AHB clock used as SysTick through the SysTick Control and by configuring Status Register. The ADC clock is generated by dividing the high-speed APB2 clock.

The timer clock frequencies are automatically fixed by hardware. There are two cases:

1. If the APB prescaler factor is 1, the timer clock frequencies are Set to the same frequency as that of the APB domain to which the timers are connected.
2. Otherwise, they are Set to twice (×2) the frequency of the APB domain to which the timers are connected.

FCLK is the free running clock.

5.2.1 HSE clock

The high speed external clock signal (HSE) can be generated from two possible clock sources:

- HSE external crystal/ceramic resonator
- HSE user external clock

The resonator and the load capacitors have to be placed as close as possible to the oscillator pins in order to minimize output distortion and startup stabilization time. The loading capacitance values must be adjusted according to the selected oscillator.

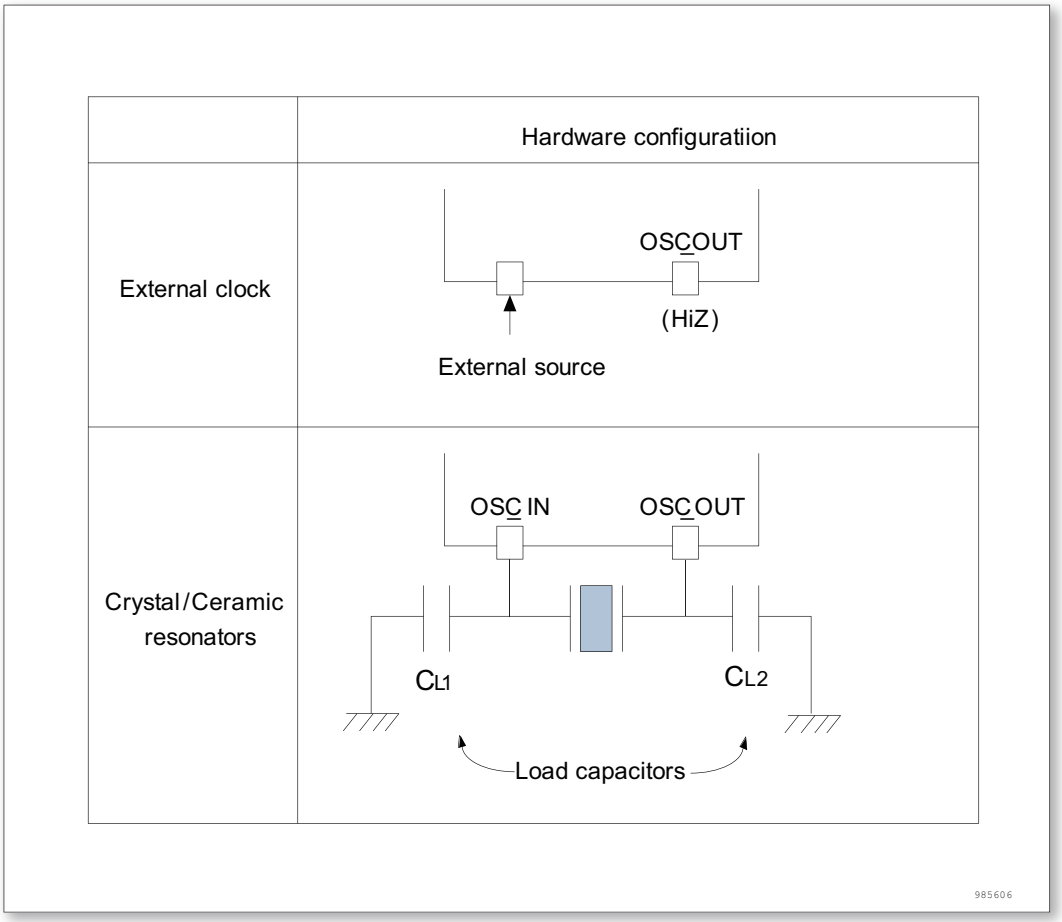

Figure 12. Clock Sources

External clock source (HSE bypass)

In this mode, an external clock source must be provided. It can have a frequency of up to 24 MHz. You can select this mode by setting the HSEBYP and HSEON bits in the Clock control register (RCC_CR). The external clock signal (square, sinus or triangle) with 50% dutycycle has to drive the OSC_IN pin while the OSC_OUT pin should be left hi-Z.

External crystal/ceramic resonator (HSE crystal)

The external oscillator has the advantage of producing a very accurate rate on the main clock. The associated hardware configuration is shown in Figure 12. Refer to the electrical characteristics section of the datasheet for more details.

The HSERDY flag in the Clock control register (RCC_CR) indicates if the high-speed external oscillator is stable or not. At startup, the clock is not released until this bit is Set to ’1’ by hardware. An interrupt can be generated if enabled in the Clock interrupt register (RCC_CIR).

The HSE Crystal can be switched on and off using the HSEON bit in the Clock control register (RCC_CR).

5.2.2 HSI clock

The HSI clock signal is generated from an internal HSI Oscillator and can be used directly as a system clock or as PLL input. The HSI oscillator has the advantage of providing a clock source at low cost (no external components). It also has a faster startup time than the HSE crystal oscillator, however, even with calibration the frequency is less accurate.

Calibration

The oscillator frequencies can vary from one chip to another due to manufacturing process variations, this is why each device is factory calibrated by ST for 1%(25°C). After reset, the factory calibration value is loaded in the HSICAL bits in the Clock control register (RCC_CR).

The HSIRDY flag in the Clock control register (RCC_CR) indicates if the HSI RC is stable or not. At startup, the HSI RC output clock is not released until this bit is Set to ’1’ by hardware. The HSI RC can be switched on and off using the HSION bit in the Clock control register (RCC_CR).

The HSI signal can also be used as a backup source (Auxiliary clock) if the HSE crystal oscillator fails. Refer to Section section 5.2.6。

5.2.3 PLL

The internal PLL can be used to multiply the HSI RC output or HSE crystal output clock frequency. Refer to Figure 11 and Clock control register (RCC_CR). The PLL configuration (selection of HSI oscillator or HSE oscillator for PLL input clock, and multiplication factor) must be done before enabling the PLL. Once the PLL is enabled, these parameters cannot be changed.

An interrupt can be generated when the PLL is ready if enabled in the Clock interrupt register (RCC_CIR).

5.2.4 LSI clock

The LSI RC acts as an low-power clock source that can be kept running in Stop and Standby mode for the independent watchdog (IWDG) and Auto-wakeup unit (AWU). The clock frequency is around 40 kHz (between 30 kHz and 60 kHz). For more details, refer to the electrical characteristics section of the datasheets.

The LSI RC can be switched on and off using the LSION bit in the Control/status register (RCC_CSR). The LSIRDY flag in the Control/status register (RCC_CSR) indicates if the low-speed internal oscillator is stable or not. At startup, the clock is not released until this bit is Set to ’1’ by hardware. An LSI interrupt request can be generated if enabled in the

Clock interrupt register (RCC_CIR).

5.2.5 System clock (SYSCLK) selection

After a system reset, the HSI oscillator is selected as system clock. When a clock source is used directly or through the PLL as system clock, it is not possible to stop it.

A switch from one clock source to another occurs only if the target clock source is ready (clock stable after startup delay or PLL locked). The switch will occur only when the clock source is ready. Status bits in the Clock configuration register (RCC_CFGR). indicate which clock(s) is (are) ready and which clock is currently used as system clock.

5.2.6 Clock security system (CSS)

Clock Security System can be activated by software. In this case, the clock detector is enabled after the HSE oscillator startup delay, and disabled when this oscillator is stopped.

If a failure is detected on the HSE clock, the HSE oscillator is automatically disabled, a clock failure event is sent to the break input of the advanced-control timers (TIM1) and an interrupt is generated to inform the software about the failure (Clock Security SystemInterrupt CSSI), allowing the software to perform rescue operations. The CSSI is linked to the CPU NMI (Non-Maskable Interrupt) exception vector.

Note: Once the CSS is enabled and if the HSE clock fails, the CSS interrupt occurs and an NMI is automatically generated. The NMI will be executed indefinitely unless the CSS interrupt pending bit is cleared. As a consequence, in the NMI ISR user must clear the CSS interrupt by setting the CSSC bit in the Clock interrupt register (RCC_CIR).

If the HSE oscillator is used directly or indirectly as the system clock (indirectly means: it is used as PLL input clock, and the PLL clock is used as system clock), a detected failure causes a switch of the system clock to the HSI oscillator and the disabling of the HSE oscillator. If the HSE clock (divided or not) is the clock entry of the PLL used as system clock when the failure occurs, the PLL is disabled too.

5.2.7 Watchdog clock

If the Independent watchdog (IWDG) is started by either hardware option or software access, the LSI oscillator is forced ON and cannot be disabled. After the LSI oscillator stabilization, the clock is provided to the IWDG.

5.2.8 Clock-out capability

The microcontroller clock output (MCO) capability allows the clock to be output onto the external MCO pin.

The registers of the corresponding GPIO port shall be configured with functions.One of 5 clock signals can be selected as the MCO clock.

- SYSCLK
- HSI
- HSE
- LSI

- PLLCLK/2
  - The selection is controlled by the MCO [2:0] bits of the Clock configuration register (RCC_CFGR).

6 General-purpose I/O(GPIO)

General-purpose I/O(GPIO)

6.1 GPIO functional description

Each of the general-purpose I/O ports has two 32-bit configuration registers (GPIOx_CRL, GPIOx_CRH), two 32-bit data registers (GPIOx_IDR and GPIOx_ODR), a 32-bit set/reset register (GPIOx_BSRR), a 16-bit reset register (GPIOx_BRR),a 32-bit locking register (GPIOx_LCKR) and two alternate-function select registers (GPIOx_AFRH) and (GPIOx_AFRL).

Each port bits of the General Purpose IO (GPIO) Ports, can be individually configured by software in several modes:

- Input floating
- Input pull-up
- Input pull-down
- Analog Input
- Output open-drain
- Output push-pull
- Alternate function push-pull
- Alternate function open-drain

Each I/O port bits is freely programmable, however, the I/O port registers have to be accessed as 32-bit words (half-word or byte accesses are not allowed).

The purpose of the GPIOx_BSRR and GPIOx_BRR registers is to allow atomic read/modify accesses to any of the GPIO registers. In this way, there is no risk that an IRQ occurs between the read and the modify access.

The following figure shows the basic structure of an I/O port bits.

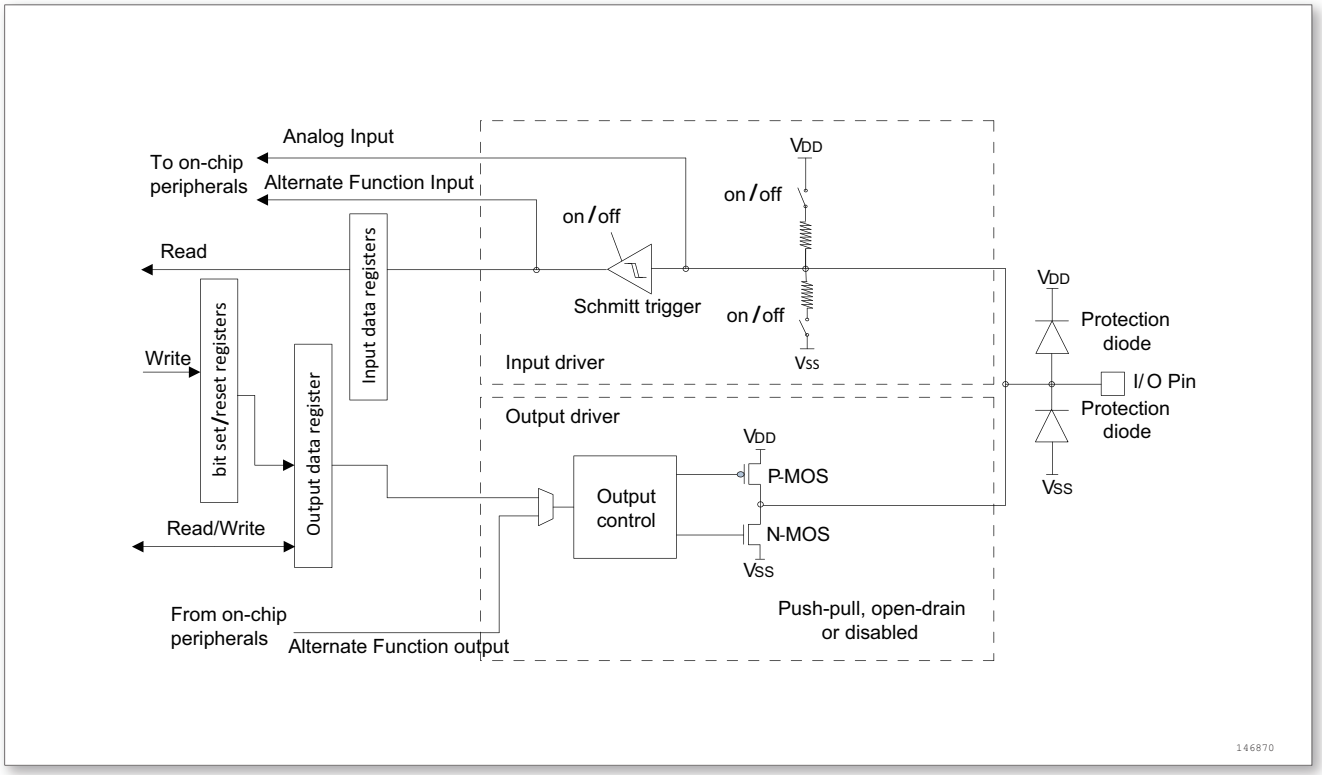

Figure 13. Basic Structure of I/O Port bits

Table 17. Port bits Configuration Table

Configuration mode		CNF1	CNF0	MODE1	MODE0	PxODR register
General purpose output	Push-Pull	0	0	01		0 or 1
	Open-Drain		1			0 or 1
Alternate function output	Push-Pull	1	0			Not used
	Open-Drain		1			Not used
Input	Analog input	0	0	00		Not used
	Input floating		1			Not used
	Input pull-down	1	0			0
	Input pull-up					1

Table 18. Output MODE bits

MODE[1: 0]	Meaning
00	Reserved
01	output

6.1.1 General-purpose I/O(GPIO)

During and just after reset, the alternate functions are not active and the I/O ports are configured in Input Floating mode (CNFx[1: 0] = 01, MODEx[1: 0] = 00).

The SWD pins are in input PU/PD after reset:

- PA14: SWCLK in PD
- PA13: SWDIO in PU

When configured as output, the value written to the Output Data Register (GPIOx_ODR) is output to the I/O pin. It is possible to use the output driver in Push-Pull mode or Open-Drain mode (only the N-MOS is activated when outputting 0).

The Input Data register (GPIOx_IDR) captures the data present on the I/O pin at every AHB clock cycle.

All GPIO pins have an internal weak pull-up and weak pull-down that can be activated or not when configured as input.

6.1.2 Atomic bits set or reset

There is no need for the software to disable interrupts when programming the GPIOx_ODR at bits level:

it is possible to modify only one or several bits in a single AHB write access.

This is achieved by programming to '1' the bits Set/Reset Register (GPIOx_BSRR, or for reset only GPIOx_BRR) to select the bits to modify. The unselected bits will not be modified.

6.1.3 External interrupt/wakeup lines

All ports have external interrupt capability. To use external interrupt lines, the port must be configured in input mode. For more information on external interrupts, refer to 7.2 External interrupt/event controller (EXTI).

6.1.4 Alternate functions

It is necessary to program the Port bits Configuration Register before using a default alternate function.

- For alternate function inputs, the port must be configured in Input mode (floating, pullup or pull-down) and the input pin must be driven externally.

Note: It is also possible to emulate the AFI input pin by software by programming the GPIO controller. In this case, the port should be configured in Alternate Function Output mode. And obviously, the corresponding port should not be driven externally as it will be driven by the software using the GPIO controller.

- For alternate function outputs, the port must be configured in Alternate Function Output mode (Push-Pull or Open-Drain).
- For bidirectional Alternate Functions, the port bits must be configured in Alternate Function Output mode (Push-Pull or Open-Drain). In this case the input driver is configured in input floating mode.

If a port bits is configured as Alternate Function Output, this disconnects the output register and connects the pin to the output signal of an on-chip peripheral. If software configures a GPIO pin as Alternate Function Output, but peripheral is not activated, its output is not specified.

6.1.5 Software remapping of I/O alternate functions

To optimize the number of peripheral I/O functions for different device packages, it is possible to remap some alternate functions to some other pins. This is achieved by software, by programming the corresponding registers (refer to AFR registers).

In that case, the alternate functions are no longer mapped to their original assignations.

6.1.6 GPIO locking mechanism

The locking mechanism allows the IO configuration to be frozen. When the LOCK sequence has been applied on a port bits, it is no longer possible to modify the value of the port bits until the next reset.

6.1.7 Input configuration

When the I/O Port is programmed as Input:

- The Output Buffer is disabled
- The Schmitt Trigger Input is activated
- The weak pull-up and pull-down resistors are activated or not depending on input configuration (pull-up, pull-down or floating);
- The data present on the I/O pin is sampled into the Input Data Register every AHB clock cycle
- A read access to the Input Data Register obtains the I/O State

The following figure shows the Input Configuration of the I/O Port bits:

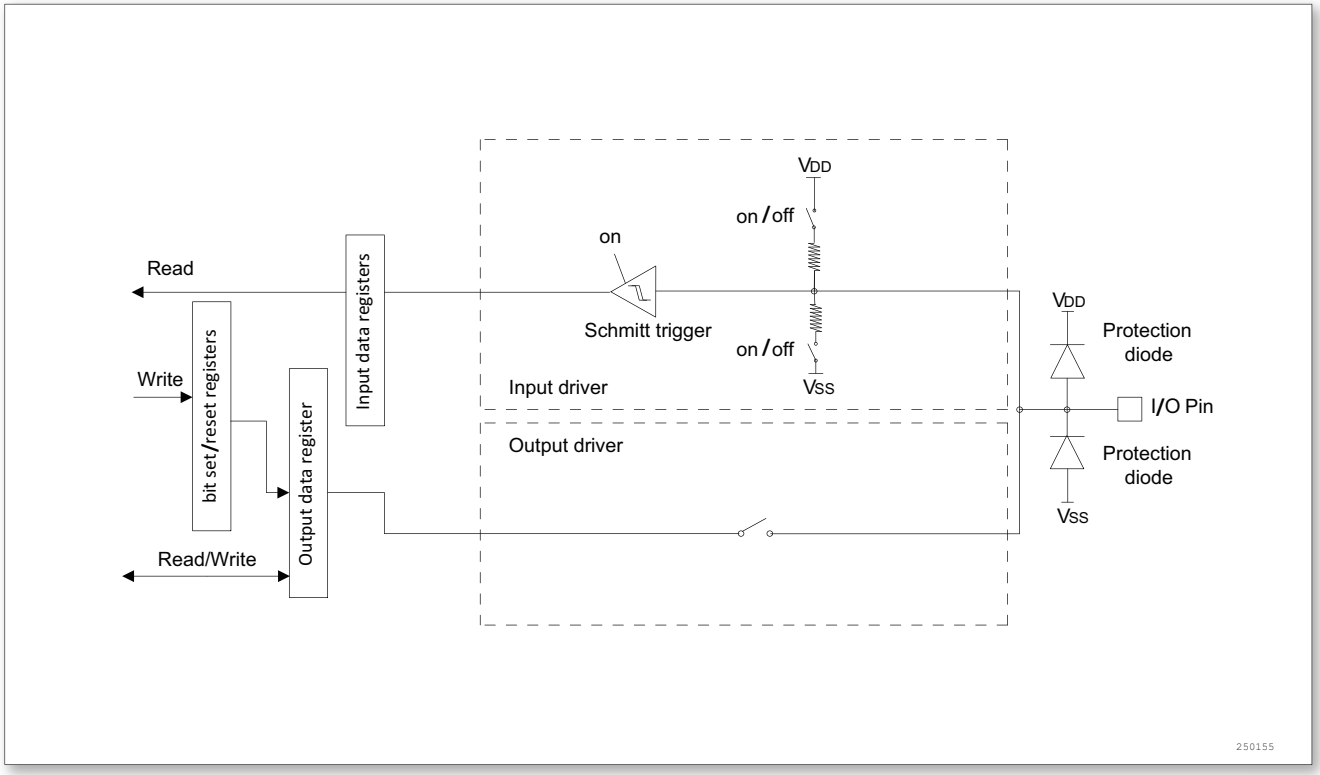

Figure 14. Input Floating/Pull Up/Pull Down Configurations

6.1.8 Output configuration

When the I/O Port is programmed as Output:

- The Output Buffer is enabled
  - Open drain mode: ’0’ on the output register activates N-MOS, and ’1’ on the output register places the port in a high-impedance state (P-MOS is never activated)
  - Push-pull mode: ’0’ on the output register activates N-MOS, and ’1’ on the output register activates P-MOS
- The Schmitt Trigger Input is activated.
- The weak pull-up and pull-down resistors are disabled.
- The data present on the I/O pin is sampled into the Input Data Register every AHB clock cycle
- A read access to the Input Data Register gets the I/O state in open drain mode
- A read access to the Output Data register gets the last written value in Push-Pull mode

The following figure shows the Output configuration of the I/O Port bits:

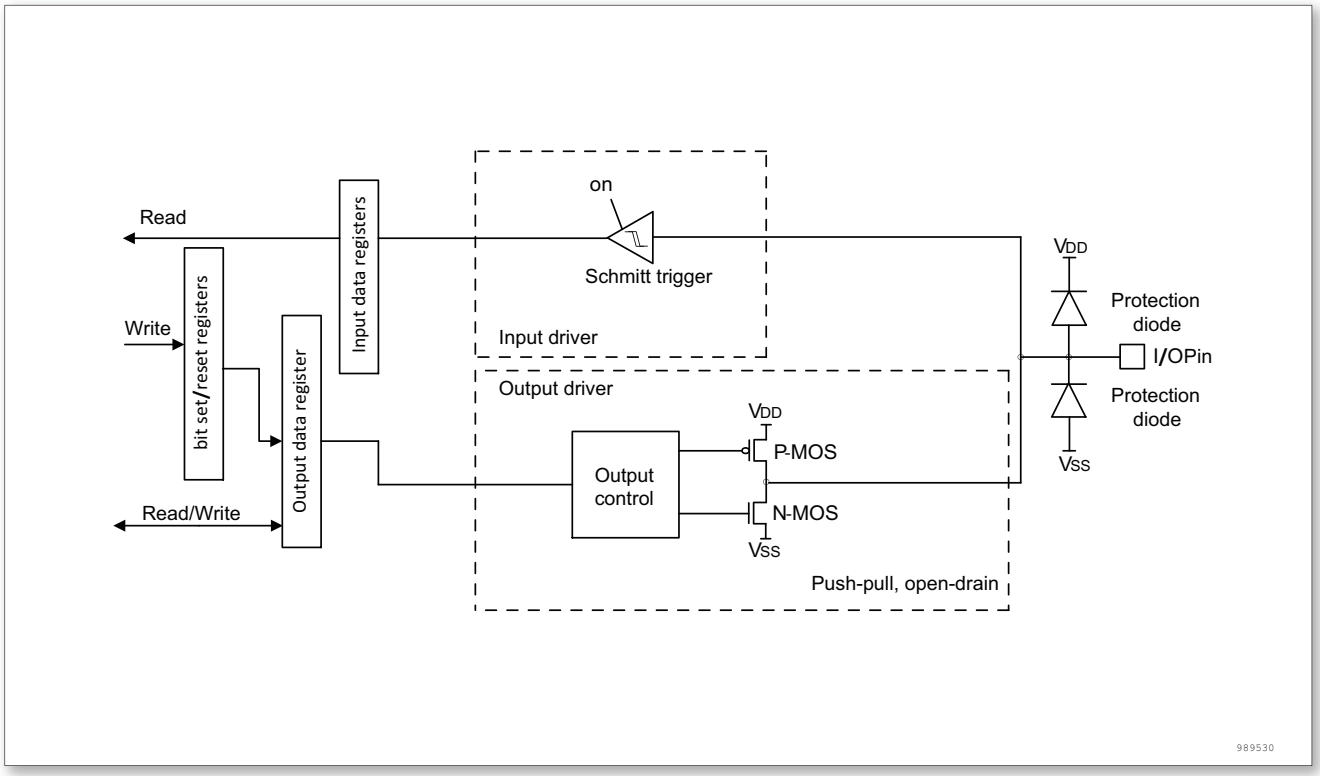

Figure 15. Output Configuration

6.1.9 Alternate functions configuration

When the I/O Port is programmed as Alternate Function:

- The Output Buffer is turned on in Open Drain or Push-Pull configuration
- The Output Buffer is driven by the signal coming from the peripheral (alternate function output)
- The Schmitt Trigger Input is activated
- The weak pull-up and pull-down resistors are disabled.

- The data present on the I/O pin is sampled into the Input Data Register every AHB clock cycle
- A read access to the Input Data Register gets the I/O state in open drain mode
- A read access to the Output Data register gets the last written value in Push-Pull mode

The following figure shows the Alternate Function Configuration of the I/O Port bits. Also, refer to AFIO registers for further information.

A set of Alternate Function I/O registers allow the user to remap some alternate functions to different pins.

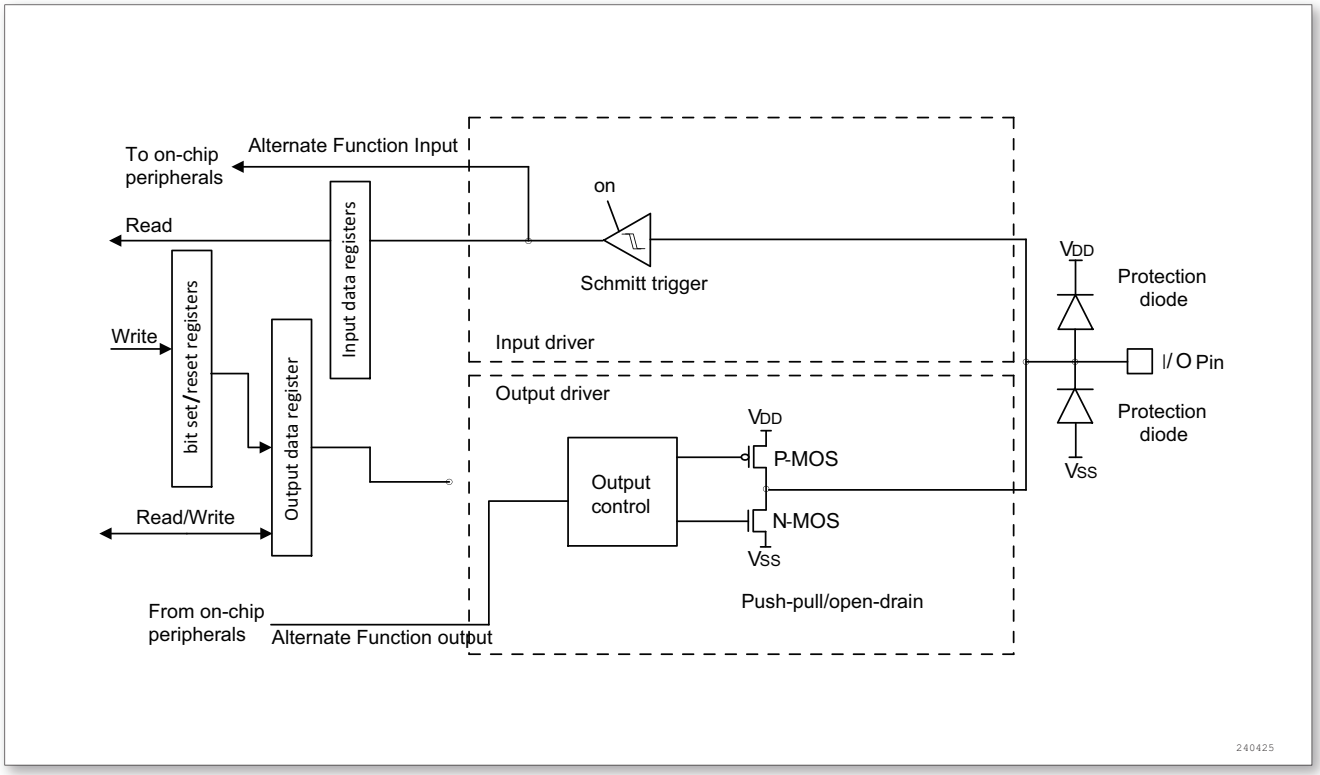

Figure 16. Alternate functions configuration

6.1.10 Analog configuration

When the I/O Port is programmed as Analog configuration:

- The Output Buffer is disabled.
- The Schmitt Trigger Input is de-activated providing zero consumption for every analog value of the I/O pin. The output of the Schmitt Trigger is forced to a constant value ’0’.
- The weak pull-up and pull-down resistors are disabled.
- Read access to the Input Data Register gets the value ’0’.

The following figure shows the high impedance-analog configuration of the I/O Port bits.

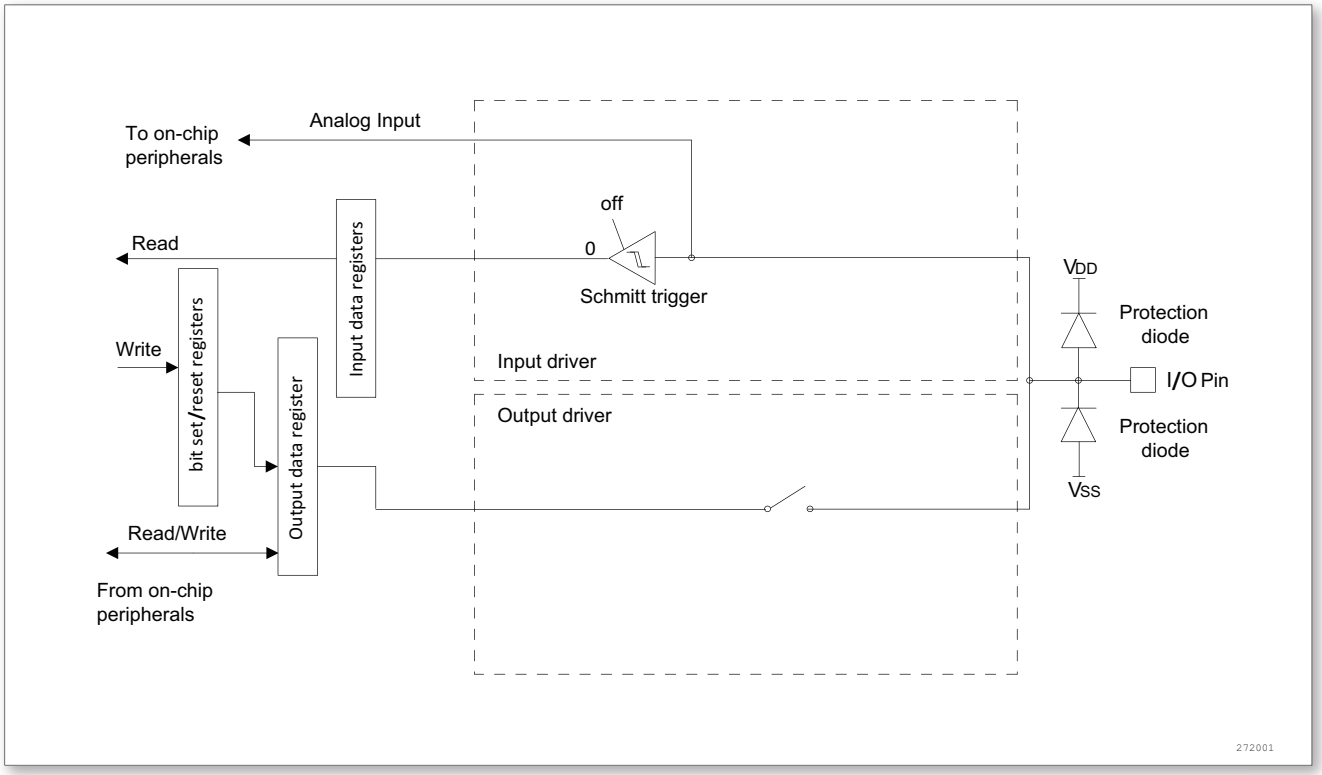

Figure 17. High Impedance-analog Configuration

6.1.11 GPIO configurations for device peripherals

The following tables give the GPIO configurations of the device peripherals:

Table 19. Advanced Timers TIM1

TIM1 pin	configuration	GPIO configuration
TIM1_CHx	Input capture channel x	Input floating
	Output compare channel x	Alternate function push-pull
TIM1_CHxN	Complementary output channel x	Alternate function push-pull
TIM1_BKIN	Break input	Input floating
TIM1_ETR	External trigger timer input	Input floating

Table 20. General-purpose timers TIM2/3/14/16/17

TIM2/3/14/16/17 pin	configuration	GPIO configuration
TIM2/3/14/ 16/17_CHx	Input capture channel x	Input floating
	Output compare channel x	Alternate function push-pull
TIM2/3_ETR	External trigger timer inputx	Input floating

Table 21. UART

UART pin	configuration	GPIO configuration
UARTx_TX	Serial-port sending	Alternate function push-pull
UARTx_RX	Serial-port receiving	Input floating/Input pull-up
UARTx_RTS	Hardware flow control	Alternate function push-pull
UARTx_CTS	Hardware flow control	Input floating/Input pull-up

Table 22. SPI

SPI pin	configuration	GPIO configuration
SPIx_SCK	Master	Alternate function push-pull
	Slave	Input floating
SPIx_MOSI	Full duplex/Master	Alternate function push-pull
	Full duplex/Slave	Input floating/Input pull-up
	Simplex bidirectional data wire/Master	Alternate function push-pull
	Simplex bidirectional data wire/Slave	Not used. Can be used as GPIO
SPIx_MISO	Full duplex/Master	Input floating/Input pull-up
	Full duplex/Slave	Alternate function push-pull
	Simplex bidirectional data wire/Master	Not used. Can be used as GPIO
	Simplex bidirectional data wire/Slave	Alternate function push-pull
SPIx_NSS	Hardware master/Slave	Input floating/Input pull-up/Input pull-down
	Hardware master /NSS output enabled	Alternate function push-pull
	Software	Not used. Can be used as GPIO

Table 23. I2C

I2C pin	configuration	GPIO configuration
I2Cx_SCL	I2C clock	Alternate function open drain
I2Cx_SDA	I2C data	Alternate function open drain

Table 24. ADC

ADC pin	GPIO configuration
ADC	Analog input

Table 25. Other I/Os

pin	configuration	GPIO configuration
MCO	Clock output	Alternate function push-pull
EXTI input lines	External input interrupts	Input floating/Input pull-up/ input pull-down

6.2 Alternate function I/O and debug configuration (AFIO)

To optimize the number of peripherals, it is possible to remap some alternate functions to some other pins. This is achieved by software, by programming the alternate function register (AFR). In this case, the alternate functions are no longer mapped to their original assignations.

6.2.1 Using OSC_IN/OSC_OUT pins as GPIO ports PD0/PD1

The external oscillator pin OSC_IN/OSC_OUT can be used as the PD0/PD1 of GPIO by disabling the internal high-speed clock and setting the alternate function register (AFR).

Note: The external interrupt/event function is not remapped.

6.2.2 SWD alternate function remapping

The debug interface signals are mapped on the GPIO ports as shown in the following table.

Table 26. Debug Interface Signals

Alternate functions	GPIO port
SWDIO	PA13
SWCLK	PA14

To optimize the number of free GPIOs during debugging, this mapping can be configured by setting the AF remap and alternate function register, so as to change the above-mentioned remapping configuration.

Bit	Field	Type	Reset	Description
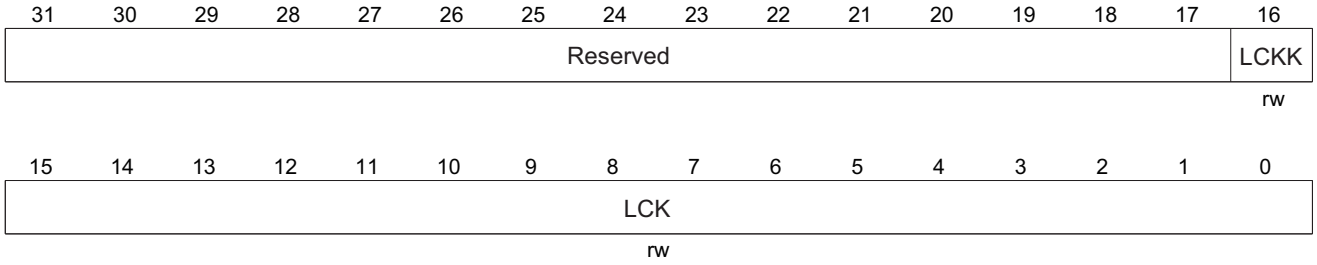
31: 16	Reserved			Always read as 0
15: 0	BRy	w	0x0000	Port x Reset bit y (y =0-15) These bits are write-only and can be accessed in Word (16 bits) mode only. 0: No action on the corresponding ODRy bit 1: Reset the corresponding ODRy bit

6.3.7 Port configuration lock register(GPIOx_LCKR)(x = A..D)

This register is used to lock the configuration of the port bits when a correct write sequence is applied to bit 16 (LCKK). The value of bits [15:0] is used to lock the configuration of the GPIO. During the write sequence, the value of LCKR[15:0] must not change. When the LOCK sequence has been applied on a port bit it is no longer possible to modify the value of the port bit until the next reset. Each lock bit freezes the corresponding 4 bits of the control register (CRL, CRH).

Address offset: 0x18

Reset value: 0x0000 0000



Bit	Field	Type	Reset	Description
31: 17	Reserved			Always read as 0
16	LCKK	rw	0x00	Lock key This bit can be read anytime. It can only be modified using the Lock Key Writing Sequence. 0: Port configuration ock key not active 1: Port configuration ock key active, GPIOx_LCKR register is locked until the next reset. LOCK key writing sequence: Write 1->Write 0->Write 1->Read 0->Read 1 The last read is optional but confirms that the lock is active. Note: During the LOCK Key Writing sequence, the value of LCK[15:0] must not change. Any error in the lock sequence will abort the lock.

Bit	Field	Type	Reset	Description
15: 0	LCKy	rw	0x00	Port x Lock bits y(y = 0…15) These bits are read and written but can only be written when the LCKK bit is 0. 0: Port configuration not locked 1: Port configuration locked

6.3.8 Port alternate-function register low(GPIOx_AFRL)(x = A..D)

Offset address: 0x20

7 Interrupts and events(EXTI)

Interrupts and events(EXTI)

7.1 Nested Vectored Interrupt Controller

Features

- Interrupts can be masked (except NMI)
- 16 programmable priority levels (4 bits of interrupt priority are used)
- Low-latency exception and interrupt handling
- Power management control
- Implementation of System Control Registers

The NVIC and the processor core interface are closely coupled, which enables low latency interrupt processing and efficient processing of late arriving interrupts.

All interrupts including the core exceptions are managed by the NVIC. For more information on exceptions and NVIC programming, refer to CPU programming manual.

7.1.1 SysTick calibration value register

The SysTick calibration value is set to 9000, which gives a reference time base of 1 ms with the SysTick clock set to 9 MHz (HCLK/8, HCLK = 72 MHz).

7.1.2 Interrupt and exception vectors

The following tables are the vector tables for the product series.

Table 28. Vectors for the Product Series

7.2 External interrupt/event controller (EXTI)

The external interrupt/event controller, consisting of edge detectors, is used for managing external and internal asynchronous events/interrupts, and for corresponding event requests sent to the CPU/ interrupt controller, and a wake-up request transmitted to the power manager.

The event/interrupt requests can be generated by the edge detector. Each input line can be independently configured to select the type (pulse or pending) and the corresponding trigger event (rising or falling or both). Each line can also be masked independently. A pending register maintains the status line of the interrupt requests.

7.2.1 Main features

The main features of EXTI controller are as follows:

- Independent trigger and mask on each interrupt/event line
- Dedicated status bit for each interrupt line
- Generation of software event/interrupt requests
- Detection of external signal with pulse width lower than APB2 clock period. Refer to the electrical characteristics section of the datasheet for details on this parameter.

7.2.2 Block diagram

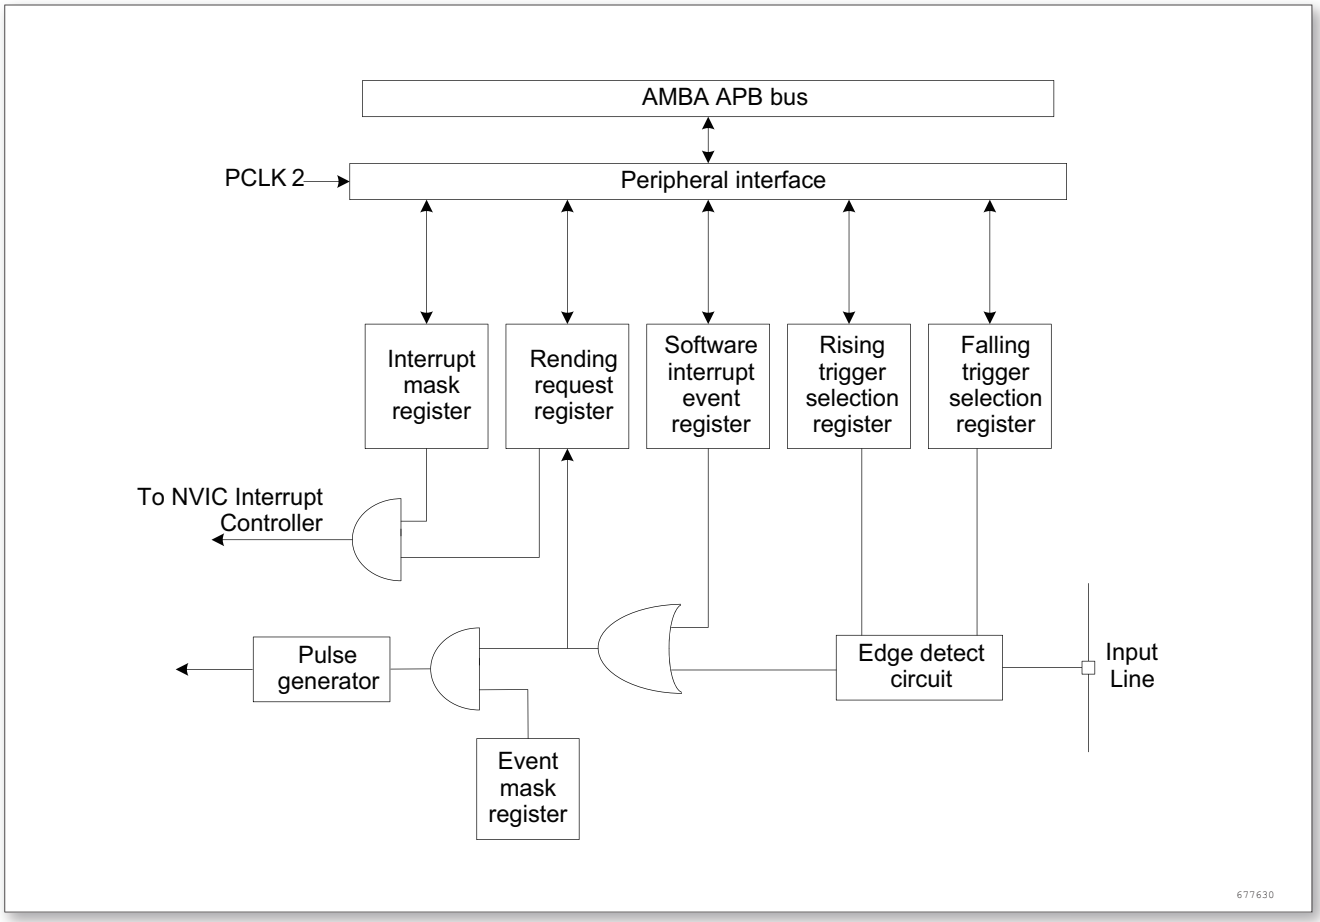

Figure 18. External Interrupt/Event Controller Block Diagram

7.2.3 Wakeup event management

The device(WFE) is able to handle external or internal events (WFE). The wakeup event can be generated either by:

- Enabling an interrupt in the peripheral control register but not in the NVIC, and enabling the SEVONPEND bit in the CPU's Control register.
  When the CPU resumes from WFE, the peripheral interrupt pending bit and the peripheral NVIC IRQ channel pending bit (in the NVIC interrupt clear pending register) have to be cleared.
- Or configuring an external or internal EXTI line in event mode. When the CPU resumes from WFE, it is not necessary to clear the peripheral interrupt pending bit or the NVIC IRQ channel pending bit as the pending bit corresponding to the event line is not set.

To use an external line as a wakeup event, refer to Section "Functional Description".

7.2.4 Functional description

To generate an interrupt, an interrupt line should be configured and enabled. This is done by programming the two trigger registers with the desired edge detection and by enabling the interrupt request by writing a '1' to the corresponding bit in the interrupt mask register. When the selected edge occurs on the external interrupt line, an interrupt request is

generated. The pending bit corresponding to the interrupt line is also set. This request is reset by writing a ‘1’ in the pending register.

To generate an event, an event line should be configured and enabled. This is done by programming the two trigger registers with the desired edge detection and by enabling the event request by writing a ‘1’ to the corresponding bit in the event mask register. When the selected edge occurs on the event line, an event pulse is generated. The pending bit corresponding to the event line is not set.

An interrupt/event request can also be generated by software by writing a ‘1’ in the software interrupt/event register.

Hardware interrupt selection

To configure the several lines as interrupt sources, use the following procedure:

- Configure the mask bits of the Interrupt lines (EXTI_IMR)
- Configure the Trigger Selection bits of the Interrupt lines (EXTI_RTSR and EXTI_FTSR)
- Configure the enable and mask bits that control the NVIC IRQ channel mapped to the External Interrupt Controller (EXTI) so that an interrupt coming from one of the lines can be correctly acknowledged.

Hardware event selection

To configure the several lines as event sources, use the following procedure:

- Configure the mask bits of the Event lines (EXTI_EMR)
- Configure the Trigger Selection bits of the Event lines (EXTI_RTSR and EXTI_FTSR)

Software interrupt/event selection

The several lines can be configured as software interrupt/event lines. The following is the procedure to generate a software interrupt.

- Configure the mask bits of the Interrupt/Event lines (EXTI_IMR, EXTI_EMR)
- Set the required bit of the software interrupt register (EXTI_SWIER)

7.2.5 External interrupt/event line mapping

The GPIOs are connected to the 16 external interrupt/event lines in the following manner:

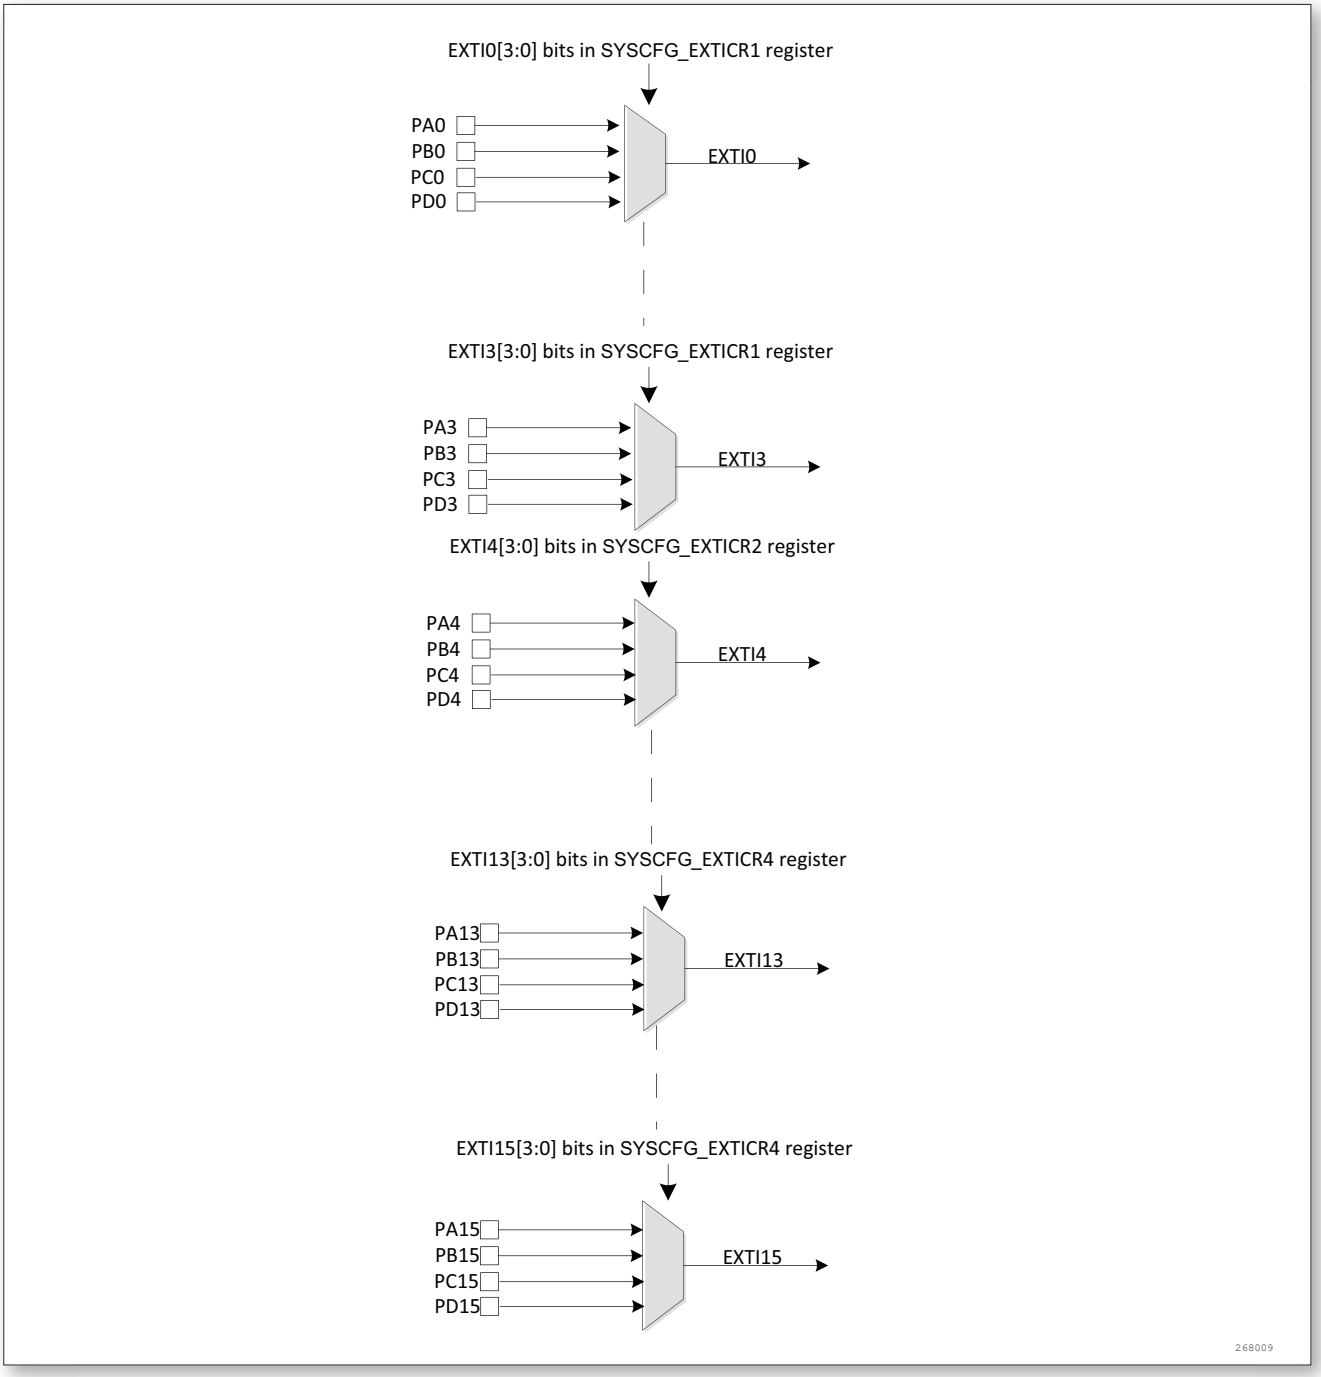

Figure 19. External Interrupt/Event GPIO Mapping

Note: GPIO corresponding to the above figure may differ due to actual chip package, and the actual package shall prevail.

The other EXTI lines are connected as follows:

- EXTI line 16 is connected to the PVD output
- EXTI line 18 is connected to USB Wakeup event
- EXTI line 19 is connected to Comparator 1 output
- EXTI line 20 is connected to Comparator 2 output

8 Direct memory access controller(DMA)

Direct memory access controller(DMA)

8.1 DMA introduction

Direct memory access (DMA) is used in order to provide high-speed data transfer between peripherals and memory as well as memory to memory. Data can be quickly moved by DMA without any CPU actions. This keeps CPU resources free for other operations.

The DMA controller has 5 channels, each dedicated to managing memory access requests from several peripherals.

8.2 DMA main features

- 5 independently configurable channels.
- Each channel is connected to dedicated hardware DMA requests, software trigger is also supported on each channel. This configuration is done by software.
- Priorities between requests from 5 channels are software-programmable (4 levels consisting of very high, high, medium, low) or hardware in case of equality (request 0 has priority over request 1, etc.)
- Independent source and destination transfer size (byte, half word, word), emulating packing and unpacking. Source/destination addresses must be aligned on the data size.
- Support for circular buffer management.
- 3 event flags (DMA Half Transfer, DMA Transfer complete and DMA Transfer Error) logically or together in a single interrupt request for each channel
- Memory-to-memory transfer
- Peripheral-to-memory and memory-to-peripheral transfers
- Access to Flash, SRAM, SRAM peripherals, APB1, APB2 and AHB peripherals as source and destination
- Programmable number of data to be transferred: up to 65536.

The block diagram is shown in the following figure:

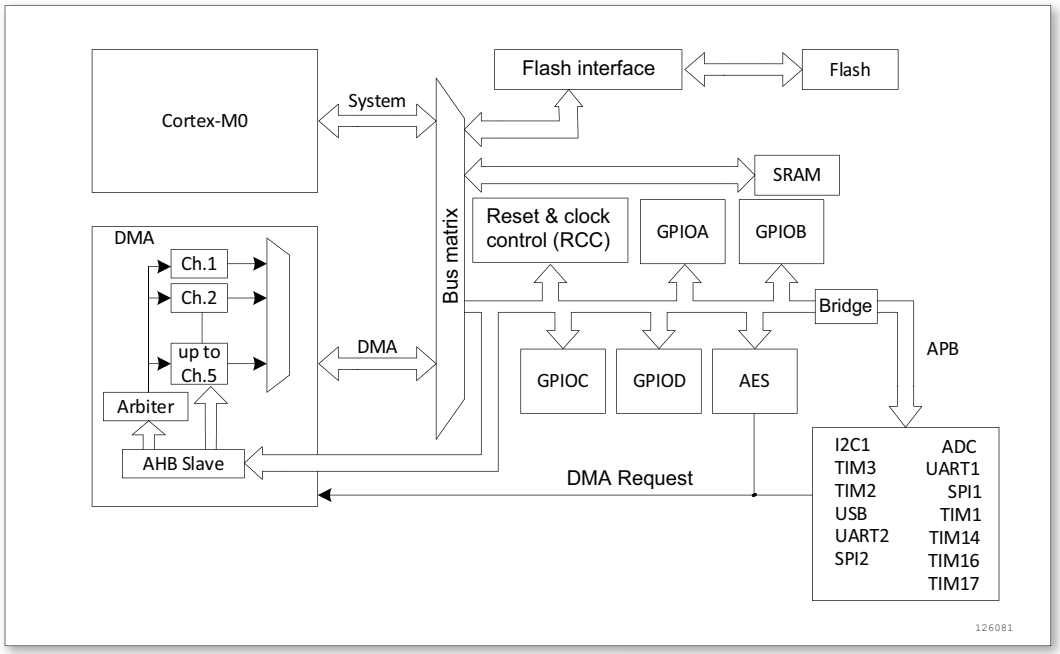

Figure 20. DMA Block Diagram

8.3 Functional description

The DMA controller performs direct memory transfer by sharing the system bus with the CPU. The DMA request may stop the CPU access to the system bus for some bus cycles, when the CPU and DMA are targeting the same destination (RAM or peripheral). The bus arbiter implements round-robin scheduling, thus ensuring at least half of the system bus bandwidth (both to memory and peripheral) for the CPU.

8.3.1 DMA transactions

After an event, the peripheral sends a request signal to the DMA Controller. The DMA controller serves the request depending on the channel priorities. As soon as the DMA Controller accesses the peripheral, an Acknowledge is sent to the peripheral by the DMA Controller. The peripheral releases its request as soon as it gets the Acknowledge from the DMA Controller. Once the request is deasserted by the peripheral, and the DMA Controller release the Acknowledge. If there are more requests, the peripheral can initiate the next transaction.

In summary, each DMA transfer consists of three operations:

1. The loading of data from the peripheral data register or a location in memory addressed through DMA_CMARx register.
2. The storage of the data loaded to the peripheral data register or a location in memory addressed through DMA_CMARx register.
3. The post-decrementing of the DMA_CNDTRx register, which contains the number of transactions that have still to be performed.

8.3.2 DMA arbiter

The arbiter manages the channel requests based on their priority and launches the peripheral/memory access sequences. The priorities are managed in two stages:

- Software: each channel priority can be configured in the DMA_CCRx register. There are four levels:
  - Very high priority
  - High priority
  - Medium priority
  - Low priority
- Hardware: if 2 requests have the same software priority level, the channel with the lowest number will get priority versus the channel with the highest number. For example, channel 2 gets priority over channel 4.

8.3.3 DMA channels

Each channel can handle DMA transfer between a peripheral register located at a fixed address and a memory address. The amount of data to be transferred (up to 65535) is programmable. The register which contains the amount of data items to be transferred is decremented after each transaction.

Programmable data sizes

Transfer data sizes of the peripheral and memory are fully programmable through the PSIZE and MSIZE bits in the DMA_CCRx register.

Pointer incrementation

Peripheral and memory pointers can optionally be automatically post-incremented after each transfer depending on the PINC and MINC bits in the DMA_CCRx register. If the incremented mode is enabled, the address of the next transfer will be the address of the previous one incremented by 1, 2 or 4 depending on the chosen data size. The first transfer address is the one programmed in the DMA_CPARx/DMA_CMARx registers. If the channel is configured in noncircular mode, no DMA request is served after the last transfer (that is once the number of data items to be transferred has reached zero).

Channel configuration procedure

The following sequence should be followed to configure a DMA channel x (where x is the channel number):

1. Set the peripheral register address in the DMA_CPARx register. The data will be moved from/ to this address to/ from the memory after the transfer request of peripheral data.
2. Set the memory address in the DMA_CMARx register. The data will be written to or read from this memory after the transfer request of peripheral data.
3. Configure the total number of data to be transferred in the DMA_CNDTRx register. After each data transmission, this value will be decremented.
4. Configure the channel priority using the PL [1:0] bits in the DMA_CCRx register.
5. Configure data transfer direction, circular mode, peripheral & memory incremented

mode, peripheral & memory data size, and interrupt after half and/or full transfer in the DMA_CCRx register.

6. Activate the channel by setting the ENABLE bit in the DMA_CCRx register. As soon as the channel is enabled, it can serve any DMA request from the peripheral connected on the channel.

Once half of the bytes are transferred, the half-transfer flag (HTIF) is set and an interrupt is generated if the Half-Transfer Interrupt Enable bit (HTIE) is set. At the end of the transfer, the Transfer Complete Flag (TCIF) is set to '1' and an interrupt is generated if the Transfer Complete Interrupt Enable bit (TCIE) is set.

Circular mode

Circular mode is available to handle circular buffers and continuous data flows (e.g. ADC scan mode). This feature can be enabled using the CIRC bit in the DMA_CCRx register. When circular mode is activated, the number of data to be transferred is automatically reloaded with the initial value programmed during the channel configuration phase, and the DMA requests continue to be served.

Memory-to-memory mode

The DMA channels can also work without being triggered by a request from a peripheral. This mode is called Memory to Memory mode. If the MEM2MEM bit in the DMA_CCRx register is set, then the channel initiates transfers as soon as it is enabled by software by setting the Enable bit (EN) in the DMA_CCRx register. The transfer stops once the DMA_CNDTRx register reaches zero. Memory to Memory mode may not be used at the same time as Circular mode.

8.3.4 Programmable data width, data alignment and endians

When PSIZE and MSIZE are not equal, the DMA performs some data alignments as described in the following table.

Table 31. Programmable Data Width and Endian Behavior (When Bits PINC = MINC = 1)

Source port width	Destination port width	Number of data items to be transferred (NDT)	Source content (address / data)	Transfer operations	Destination content (address / data)

Addressing an AHB peripheral that does not support byte or halfword write operations

When the DMA initiates an AHB byte or halfword write operation, the data are duplicated

on the unused lanes of the HWDATA[31:0] bus. So when the used AHB slave peripheral does not support byte or halfword write operations (when HSIZE is not used by the peripheral) and does not generate any error, the DMA writes the 32 HWDATA bits as shown in the two examples below:

- To write the halfword “0xABCD”, the DMA sets the HWDATA bus to “0xABCDABCD” with HSIZE = HalfWord
- To write the byte “0xAB”, the DMA sets the HWDATA bus to “0xABABABAB” with HSIZE = Byte ‘0xABABABAB’.

Assuming that the AHB/APB bridge is an AHB 32-bit slave peripheral that does not take the HSIZE data into account, it will transform any AHB byte or halfword operation into a 32-bit APB operation in the following manner:

- an AHB byte write operation of the data “0xB0” to 0x0 (or to 0x1, 0x2 or 0x3) will be converted to an APB word write operation of the data “0xB0B0B0B0” to 0x0.
- an AHB halfword write operation of the data “0xB1B0” to 0x0 (or to 0x2) will be converted to an APB word write operation of the data “0xB1B0B1B0” to 0x0.

For instance, to write the APB backup registers (16-bit registers aligned to a 32-bit address boundary), the memory source size (MSIZE) must be configured to “16-bit” and the peripheral destination size (PSIZE) to “32-bit”.

8.3.5 Error management

A DMA transfer error can be generated by reading from or writing to a reserved address space. When a DMA transfer error occurs during a DMA read or a write access, the faulty channel is automatically disabled through a hardware clear of its EN bit in the corresponding Channel configuration register (DMA_CCRx). The channel’s transfer error interrupt flag (TEIF) in the DMA_IFR register is set and an interrupt is generated if the transfer error interrupt enable bit (TEIE) in the DMA_CCRx register is set.

8.3.6 Interrupts

An interrupt can be produced on a Half-transfer, Transfer complete or Transfer error for each DMA channel. Separate interrupt enable bits are available for flexibility.

Table 32. DMA Interrupt Requests

Interrupt event	Event flag	Enable Control bit
Half-transfer	HTIF	HTIE
Transfer complete	TCIF	TCIE
Transfer error	TEIF	TEIE

8.3.7 DMA request mapping

DMA controller

The 5 requests from the peripherals TIMx、ADC、SPI、I2C and UART are simply logically ORed before entering the DMA1, this means that only one request must be enabled at a

time. Refer to the following figure.

The peripheral DMA requests can be independently activated/de-activated by programming the DMA control bit in the registers of the corresponding peripheral.

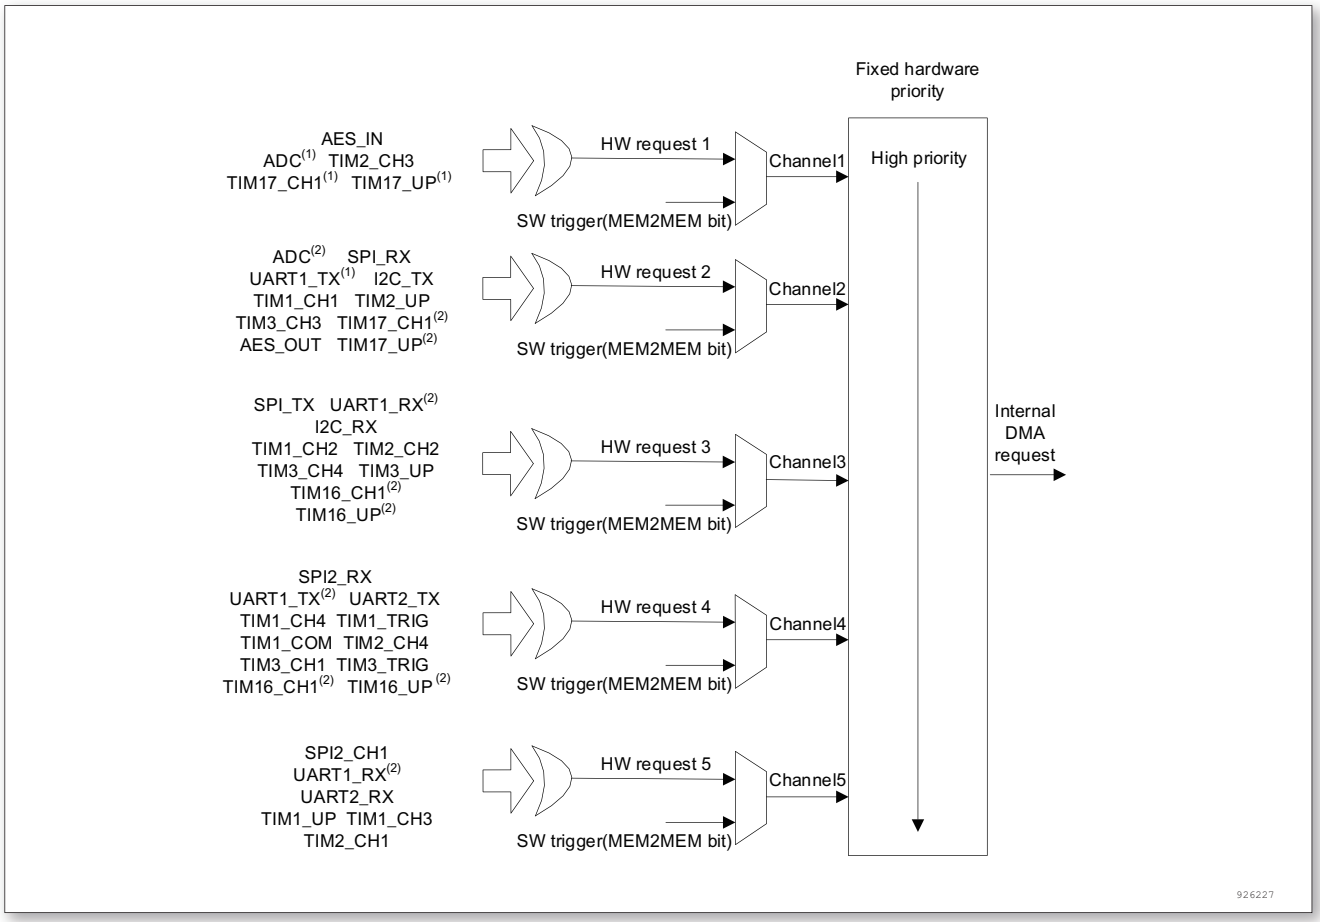

Figure 21. Peripheral DMA Request Mapping

Table 33. Summary of DMA Requests for Each Channel

Peripherals	Channel 1	Channel 2	Channel 3	Channel 4	Channel 5
ADC	ADC1(1)	ADC1(2)			
SPI		SPI1_RX	SPI1_TX	SPI2_RX	SPI2_TX
UART		UART1_TX(1)	UART1_RX(1)	UART1_TX(2) UART2_TX	UART1_RX(2) UART2_RX
I2C		I2C1_TX	I2C1_RX		
TIM1		TIM1_CH1	TIM1_CH2	TIM1_CH4 TIM1_TRIG TIM1_COM	TIM1_UP TIM1_CH3
TIM2	TIM2_CH3	TIM2_UP	TIM2_CH2	TIM2_CH4	TIM2_CH1
TIM3		TIM3_CH3	TIM3_CH4 TIM3_UP	TIM3_CH1 TIM3_TRIG	
TIM16			TIM16_CH1(1) TIM16_UP(1)	TIM16_CH1(2) TIM16_UP(2)	

Peripherals	Channel 1	Channel 2	Channel 3	Channel 4	Channel 5
TIM17	TIM17_CH1(1) TIM17_UP(1)	TIM17_CH1(2) TIM17_UP(2)			
AES	AES_IN	AES_OUT			

1. If the mapping bit in SYSCFG_CFGR register is cleared, the DMA request is mapped on the DMA channel.
2. If the mapping bit in SYSCFG_CFGR register is set, the DMA request is mapped on the DMA channel.

9 Analog-to-digital converter(ADC)

Analog-to-digital converter(ADC)

9.1 ADC introduction

The 12-bit ADC is a successive approximation analog-to-digital converter.

A/D conversion of the various channels can be performed in single, continuous, scan mode, and you can choose automatic channel scanning.

Its start-up mode includes the software setting, external pin triggering and activated by timers.

The window comparator (analog watchdog) allows the application to detect if the input voltage goes outside the user-defined high or low thresholds.

The ADC input clock is generated from the PCLK2 clock divided by a prescaler and it must not exceed 15 MHz.

9.2 ADC main features

- 12-bit-resolution SAR ADC, up to 10 external input channels and 2 internal input channels
- Up to 1 Msps conversion rate
- Supporting multiple operation modes:
  - Single conversion mode: one A/D conversion in specified channel
  - Single-cycle scanning mode: one A/D conversion cycle (from low-number channel to high-number channel) completed in all designated channels
  - Continuous scan mode: A/D converter continuously performs single-cycle scanning until the converter is disabled by software
- Channel sampling time and resolution can be configured by software
- Support DMA transfer
- Conditions of A/D conversion:
  - By software
  - External triggering
  - Timer matching
- In terms of analog watchdog, the conversion result can be compared with the specified value; the user can set whether to generate an interrupt request or not when the conversion value matches the set value.

9.3 ADC functional description

The ADC block diagram is as shown below.

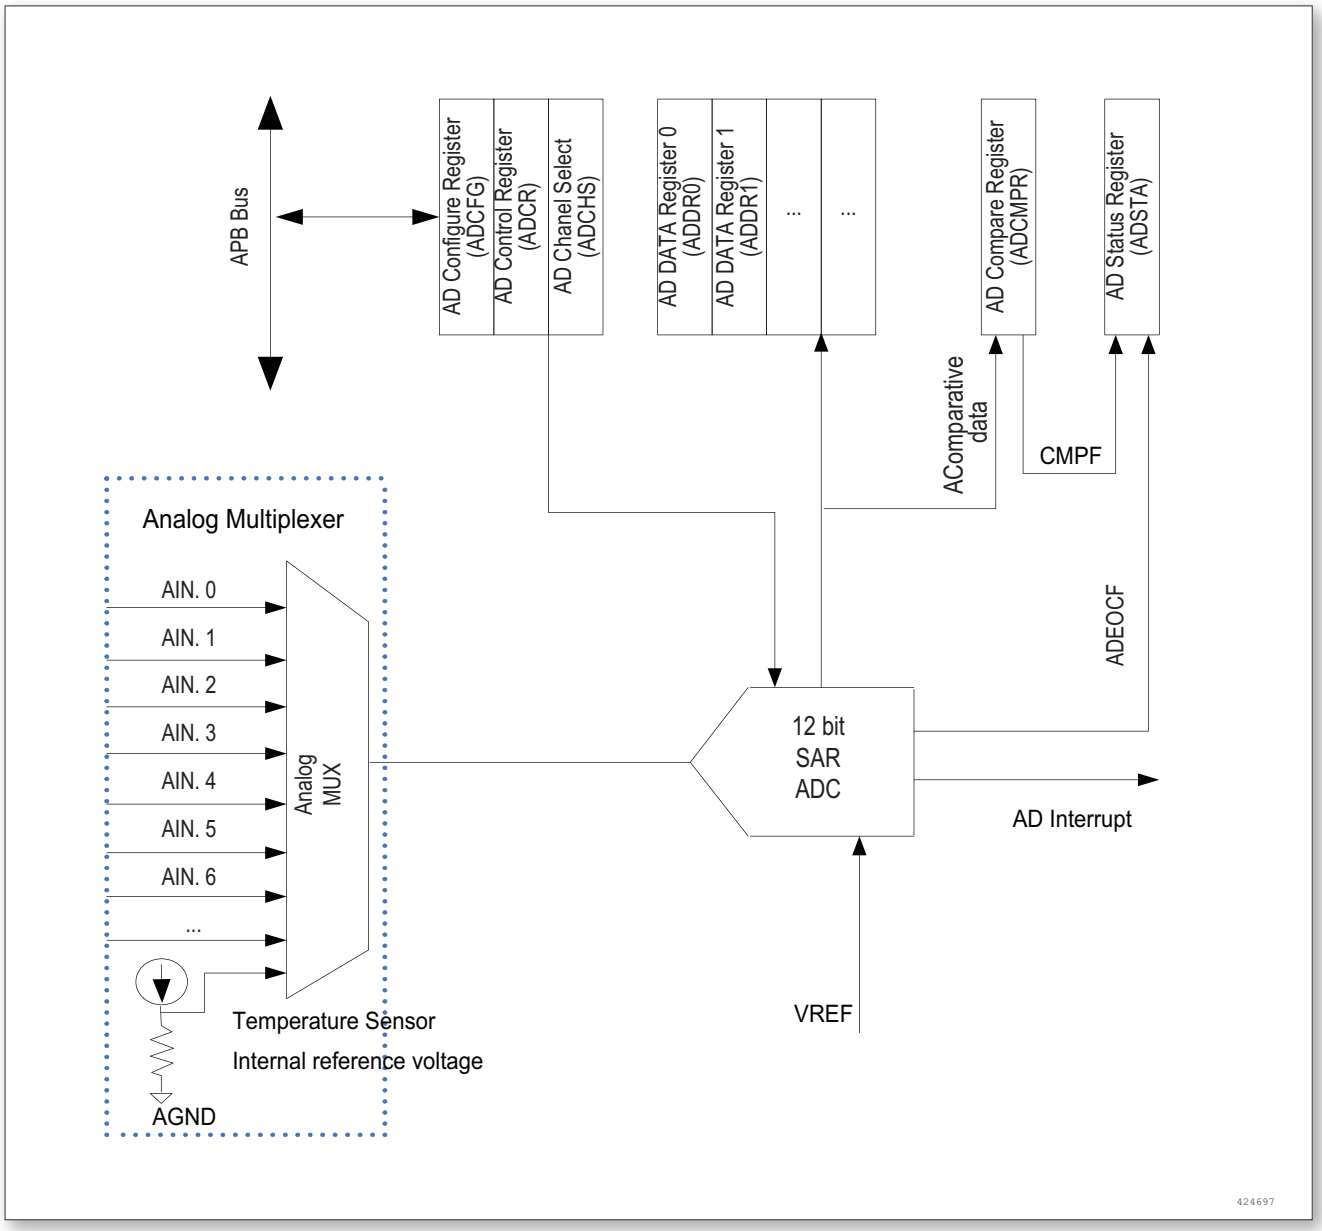

Figure 22. ADC block diagram

9.3.1 ADC on-off control

The ADC can be powered-on by setting the ADEN bit in the ADCFG register. When the ADEN bit is set for the first time, it wakes up the ADC from Power Down mode.

Conversion starts when ADST bit of ADCR register is set after ADC power-up time.

The conversion can be stopped by clearing the ADST bit, and the ADC put in power down mode by resetting the ADEN bit.

9.3.2 Channel selection

There are several external input channels, internal temperature sensor channel and internal 1.2 V reference voltage channel. Among them, each external input channel has independent enabling bit, which can be configured by setting bits concerned of the AD-

CHS register.

9.4 ADC operating mode

9.4.1 Single conversion mode

In the single conversion mode, the A/D conversion is only performed once on the corresponding channel, and the specific process is as follows:

- The A/D conversion is activated by software, external trigger input, and the ADST bit of the timer overflow setting ADCR register.
- After the A/D conversion, the data value concerned will be saved in the ADDATA and ADDRn data registers of A/D converter.
- ADIF bit of status register ADSTA is set to '1' after the A/D conversion. If ADIE bit of control register ADCR is set to '1' at this time, an AD conversion end interrupt request will be generated.
- During the A/D conversion, the ADST bit remains 1. After that, the ADST bit is cleared automatically and the idle mode is enabled.

Note: If the software, in the single conversion mode, enables more than one channel, the channel with the smallest number will be converted and other channels will be ignored.

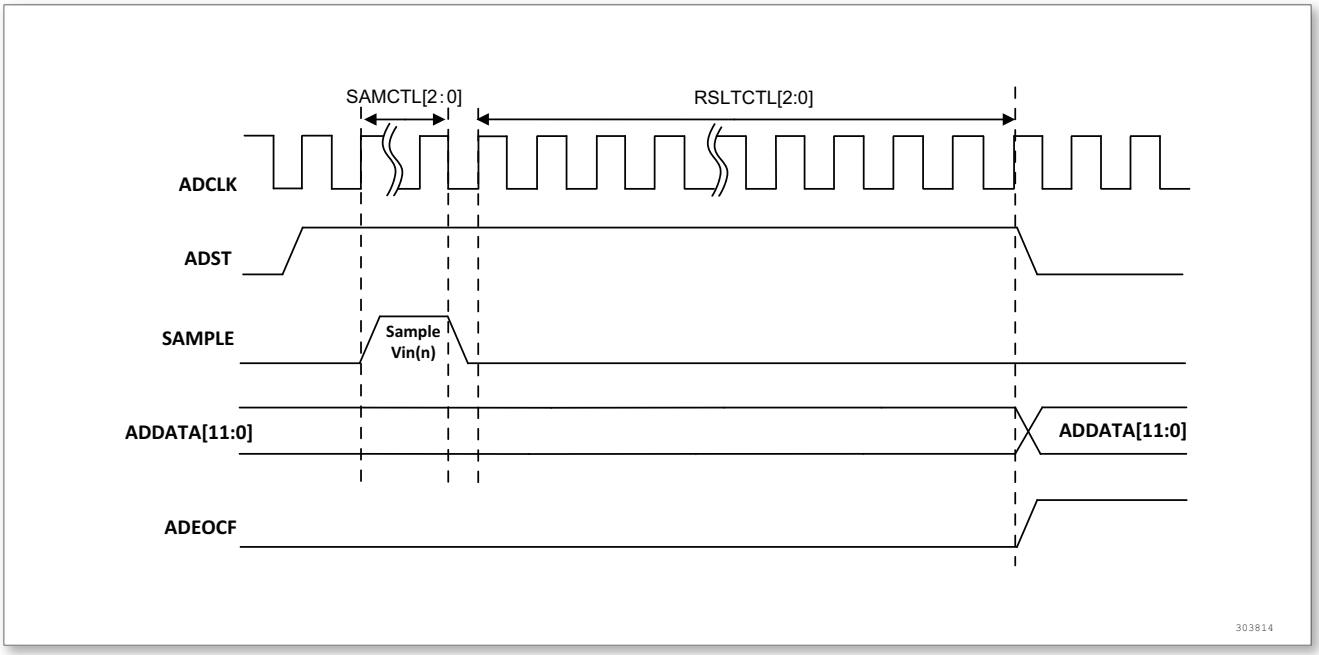

Figure 23. Timing Diagram of Single Conversion Mode

9.4.2 Single-cycle scan mode

- Starting from the software or external trigger setting bit ADST, the A/D conversion is enabled from the channel with the minimum number to that with the maximum number.
- After A/D conversion in each channel, the A/D conversion values will be loaded into the data registers in the corresponding channels in an orderly manner, and the ADIF conversion end flag will be set. If the conversion end interrupt flag is set, an interrupt request will be generated after the conversion in all channels.

- After the conversion, ADST bit is cleared automatically, so that A/D converter enters idle state.

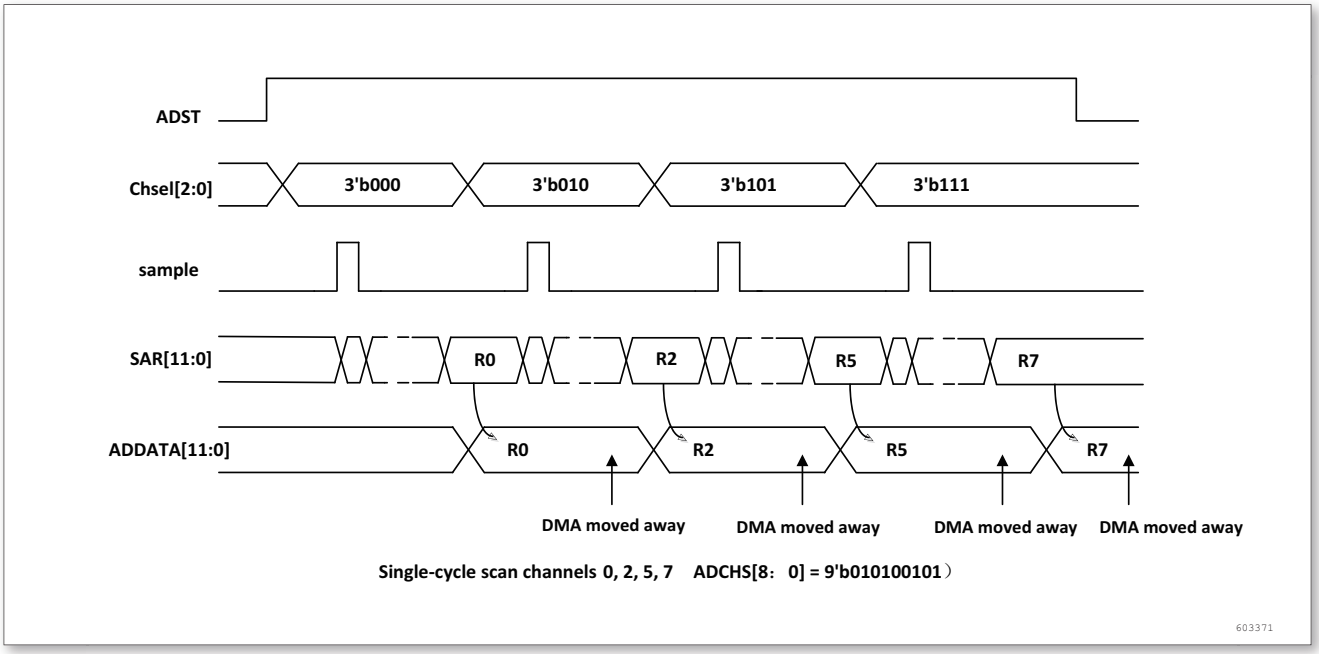

Figure 24. Timing Diagram of Enabled Channel During Conversion in Single-cycle Scan Mode

9.4.3 Continuous scan mode

In the continuous scan mode, A/D conversion is performed sequentially in the channel where the CHENn bit in the ADCHS register is enabled. The operation steps are as follows:

- Starting from the software or external trigger setting bit ADST, the A/D conversion is enabled from the channel with the minimum number to that with the maximum number.
- After A/D conversion in all channels, the A/D conversion values will be loaded into the data registers concerned in an orderly manner, and the ADIF conversion end flag will be set. If the conversion end interrupt flag is set, an interrupt request will be generated after the conversion in all channels.
- As long as the ADST bit remains 1, the A/D conversion continues. When ADST bit is cleared and A/D conversion is completed, A/D converter enters the idle mode. When ADST is cleared, the current A/D conversion will be completed.

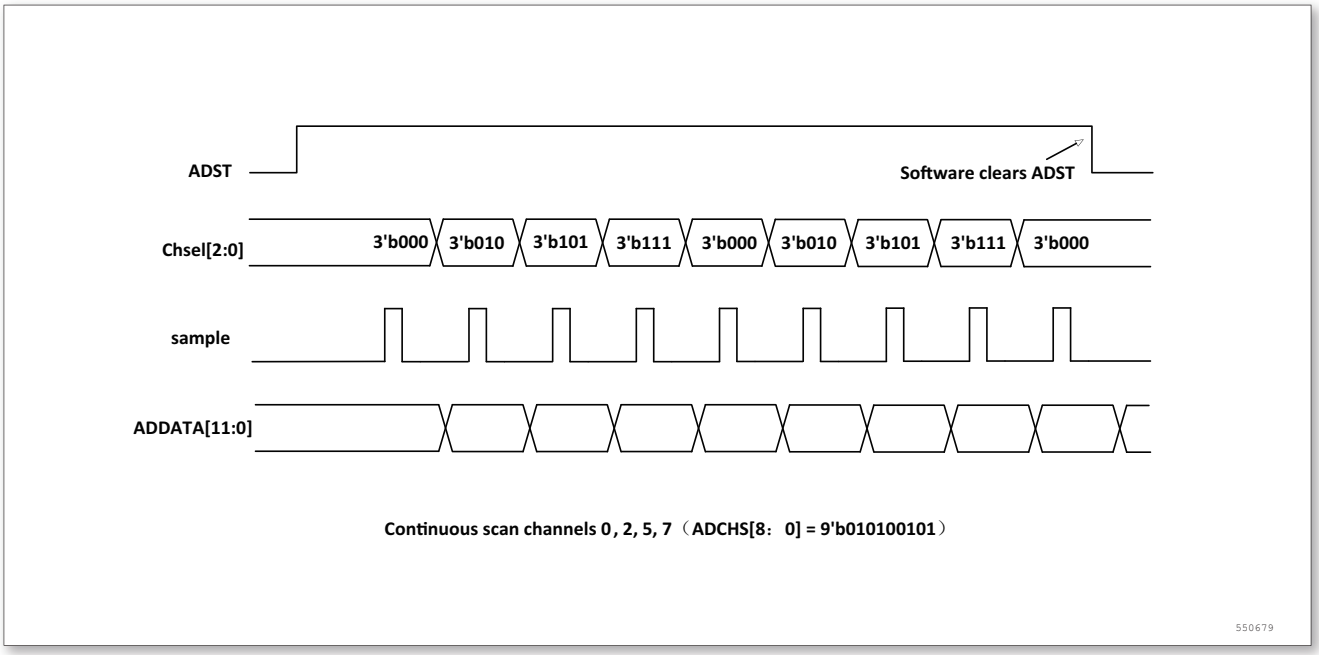

Figure 25. Timing Diagram of Enabled Channel During Conversion in Continuous Scan Mode

9.4.4 DMA request

In the single-cycle scan and continuous scan modes, the value of channel conversion is saved in the data registers (ADDRn) in respective channel, and the result of the latest conversion is also stored in the ADDATA register. During DMA transmission, you can choose to transfer data in a specific channel or transfer the results of all scanning channels.

9.5 Data alignment

ALIGN bit in the ADCR register selects the alignment of data stored after conversion. Data can be left or right aligned as shown in the following figure .

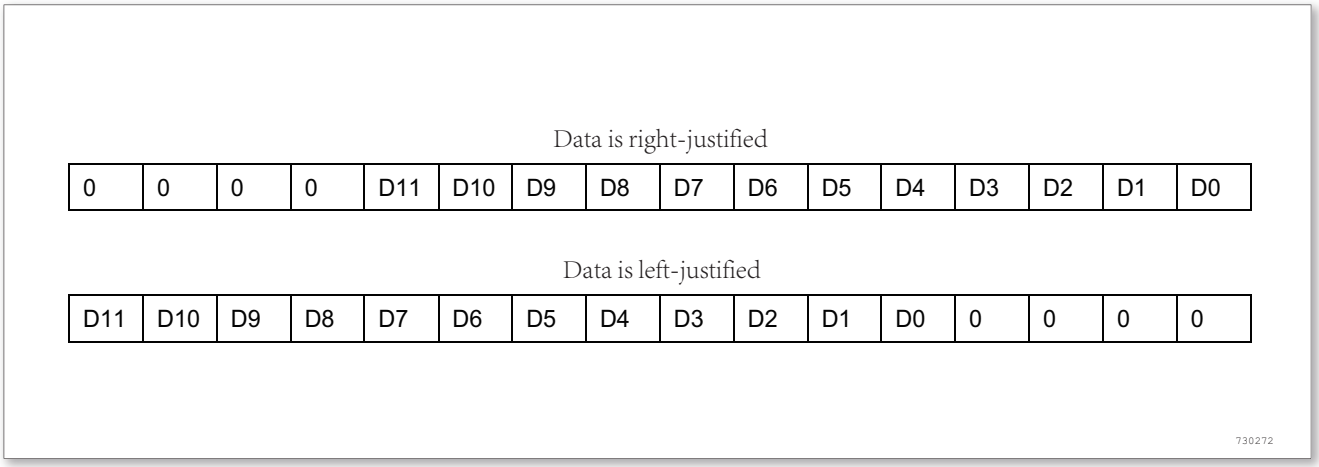

Figure 26. Data Alignment Modes

9.5.1 Programmable resolution

The effective ADC conversion bits can be changed by modifying RSLT CTL [2: 0] bits in ADC_CFG register, to improve the data conversion rate. The effective data bits are

aligned at the high bits of 12-bit data.

9.5.2 Programmable sample time

ADCLK, the ADC clock, is generated by dividing PCLK2, and its division factor can be determined by setting the AD-CPRE bit in ADCFG bit, namely, the PCLK2 / (N + 1) / 2 is used as the ADC clock.

The ADC resolution is n (n=8, 9, 10, 11 and 12), the sampling period in each channel is m, and the number of sampling periods can be modified through the SAMCTL bits in the ADC_CFG registers.

The sampling frequency and sampling time are calculated as follows:

$F_{sample} = F_{ADCLK} / (m + n + 1.5)$.

Example:

With an ADCCLK = 15MHz, the resolution of 12 bits and a sampling time of 1.5 cycles

$F_{sample} = F_{ADCLK} / 15$.

$T_{CONV} = 1.5 + 13.5 = 15$ cycles = 1μs

9.6 Conversion on external trigger

Conversion can be triggered by an external event (e.g. timer capture, EXTI line). If the TRGEN bit of ADCR register is set, then external events are able to trigger a conversion. By setting the TRGSEL bits, the external trigger sources can be selected.

For the selection of specific external trigger sources, please refer to the description of relevant bits in AD control register.

The sampling is initiated after the generation of trigger signal and N PCLK2 cycles. In the trigger scan mode, only the sampling of the first channel is delayed, and the rest channels is sampled immediately after the end of the previous operation.

9.7 Temperature sensor

The temperature sensor can be used to measure the ambient temperature (T_A) of the device.

The temperature sensor is internally connected to the ADC input channel which is used to convert the sensor output voltage into a digital value. When not in use, this sensor can be disabled separately by setting relevant bits of the register.

The temperature sensor output voltage changes linearly with temperature. The offset of this line varies from chip to chip due to process variation.

The internal temperature sensor is more suited to applications that detect temperature variations instead of absolute temperatures. If accurate temperature readings are needed, an external temperature sensor part should be used.

The temperature is calculated as follows:

$T(°C) = (V_{SENSE} - V_{25}) / Avg\_Slope + 25$

V_{25}: V_{SENSE} value for 25°C

V_{SENSE}: the current output voltage of temperature sensor

V_{SENSE} = Value * V_{dd} / 4096 (Value is the conversion result of ADC)

Avg_Slope: Average Slope for curve between Temperature vs. V_{SENSE}(given in mV/°C or μV/°C)

Refer to the temperature sensor section for the actual values of V_{25} and Avg_Slope.

9.8 Internal reference voltage

The input channel of ADC is loaded with an internal reference voltage (1.2V), converting the reference voltage output of 1.2V into a digital value.

The internal reference voltage has a separate enable bit, which can be enabled or disabled by setting the corresponding bit in the register.

9.9 Monitoring of AD conversion results in window comparator mode

The upper limit and lower limit compare registers are enabled in the comparison mode, and the CMPCH bit can be set by software, to select the monitoring channel.

If CPMHDATA is ≥ CPMLDATA, and the comparison result is greater than or equal to the specified value of CMPHDATA in the ADCMPR register or less than the specified value of CMPLDATA, the ADWIF bit of the status register ADSTA is set to 1.

If CPMHDATA is < CPMLDATA and the comparison result is equal to the specified value of CMPHDATA or between the two specified value, the ADWIF bit of the status register ADSTA is set to 1. An interrupt request will be generated if ADWIE bit of the control register ADCR is set. An interrupt request will be generated if ADWIE bit of the control register ADCR is set.

15 : 0	DATA	r	0x00	Transfer data(12-bit A/D conversion result on channel) Left alignment or right alignment, depending on specific settings.

10 Comparator(COMP)

Comparator(COMP)

10.1 COMP introduction

Two universal comparators, COMP1 and COMP2, are embedded in the chip and can be used independently (applicable to I/O ports on all terminals) or used in combination with timers. They support various functions, including:

- Trigger the wakeup event in the low power consumption mode through the analog signal
- Adjust analog signal
- Form a cycle-by-cycle current control loop in combination with PWM output by timer

The comparator, a universal programmable voltage comparator, can be used independently and is applicable to I/O ports on all terminals. Two comparators support separate operating mode.

10.2 Main features of comparator

- Rail-to-rail comparator
- Each comparator has optional thresholds
  - Reusable I/O pins
  - Internal reference voltage and three voltage division (1/4, 1/2, and 3/4)
- Programmable latency voltage
- Programmable rate and power consumption
- The output can be redirected to one I/O port or several timer inputs, to trigger the following events:
  - Capture event
  - OCref_clr event (cycle-by-cycle current control)
  - Break event enabling fast PWM shutdown
- Two comparators can be integrated in one window comparator for operation.
- Each comparator can trigger interrupts and wake up the CPU from sleep and shutdown modes (via EXTI controller).

10.3 Functional description of comparator

10.3.1 Introduction

The following figure is a block diagram of the comparator.

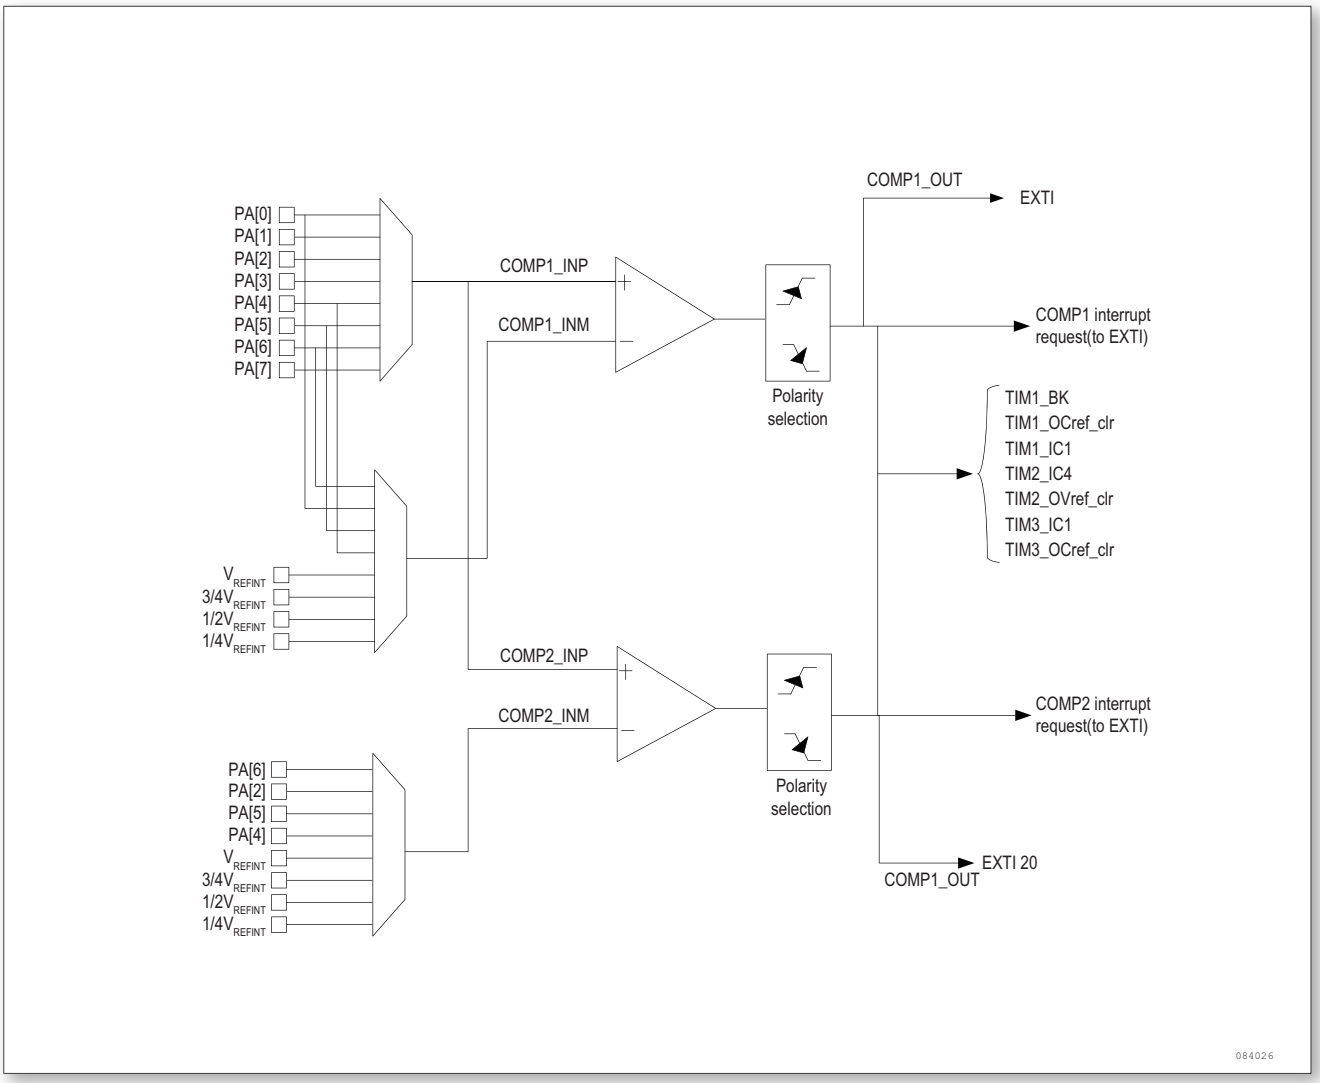

Figure 27. Comparator Block Diagram

10.3.2 Clock

The clock, provided by the COMP clock controller, is synchronized with PCLK (APB2 clock). Before using the comparator, enable the clock enable control bit in the RCC controller.

10.3.3 Comparator input and output

The I/O pin as the comparator input shall be set to the analog mode in the GPIO register.

The comparator output can be internally redirected to various timer inputs:

- As break input, disabling the PWM signal in emergency mode
- As OCref_clr, enabling cycle-by-cycle current control
- As input capture, measuring time sequence

10.3.4 Interrupt and wakeup

The output of the comparator can be internally connected to an external interrupt and event controller. Each comparator has its own EXTI signal, enabling triggering interrupts

or events. The same mechanism can be used to exit from the low power mode.

Refer to Interrupts and events section of the datasheet for details.

10.3.5 Power consumption mode

In specific applications, the optimal results can be obtained by adjusting the power consumption and response time of the comparator.

The MODE bit in the COMPx_CSR register is configured as follows:

- 00: High speed/high power consumption
- 01: Medium speed/medium power consumption
- 10: Low speed/low power consumption
- 11: Very low speed/very low power consumption

10.3.6 Comparator locking mechanism

Comparators can be used for safety purposes, such as overcurrent or overheat protection. In some applications with specific requirements, it is necessary to ensure that comparator settings will not be changed by invalid register access or failure of program counter.

For this purpose, the comparator control and status registers can be write-protected (read-only).

Once being configured, the LOCK bit shall be set to 1, making the entire COMPx_CSR register read-only, including the LOCK bit. The write protection can only be cleared by resetting MCU.

10.3.7 Latency

The configurable latency voltage of the comparator can prevent noise signals generated by invalid output changes, and the latency can be disabled without latency voltage .

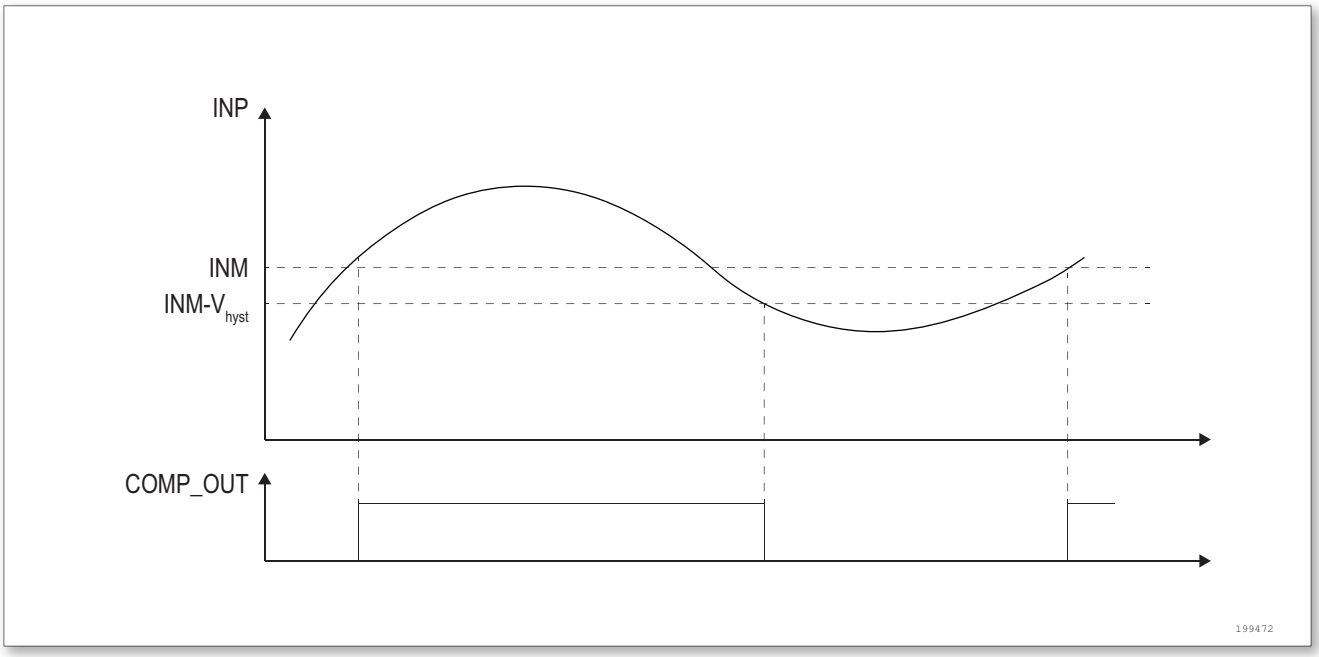

Figure 28. Comparator Latency

Advanced-control timer(TIM1)

11.1 TIM1 introduction

Advanced-control timer(TIM1) consists of a 16-bit auto-reload counter driven by a programmable prescaler.

It may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare, PWM, complementary PWM with dead-time insertion).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The advanced-control (TIM1) and general-purpose (TIMx) timers are completely independent, and do not share any resources. They can be synchronized together as described in Section Timer Synchronization.

11.2 Main features

TIM1 functions include:

- 16-bit up, down, up/down auto-reload register
- 16-bit programmable prescaler allowing dividing (modifing in real time) the counter clock frequency either by any factor between 1 and 65536.
- Up to 4 independent channels for:
  - Input capture
  - Output compare
  - PWM generation (Edge and Center-aligned Mode)
  - One-pulse mode output
- outputs with programmable dead-time
- circuit to control the timer with external signals and to interconnect several timers together.
- counter to update the timer registers only after a given number of cycles of the counter
- input to put the timer’s output signals in reset state or in a known state
- Interrupt/DMA generation on the following events:
  - Update: counter overflow/underflow, counter initialization (by software or internal/external trigger)
  - Trigger event (counter start, stop, initialization or count by internal/external trigger)
  - Input capture

- Output compare
- Break input

- Supports incremental (quadrature) encoder and hall-sensor circuitry for positioning purposes
- Trigger input for external clock or cycle-by-cycle current management

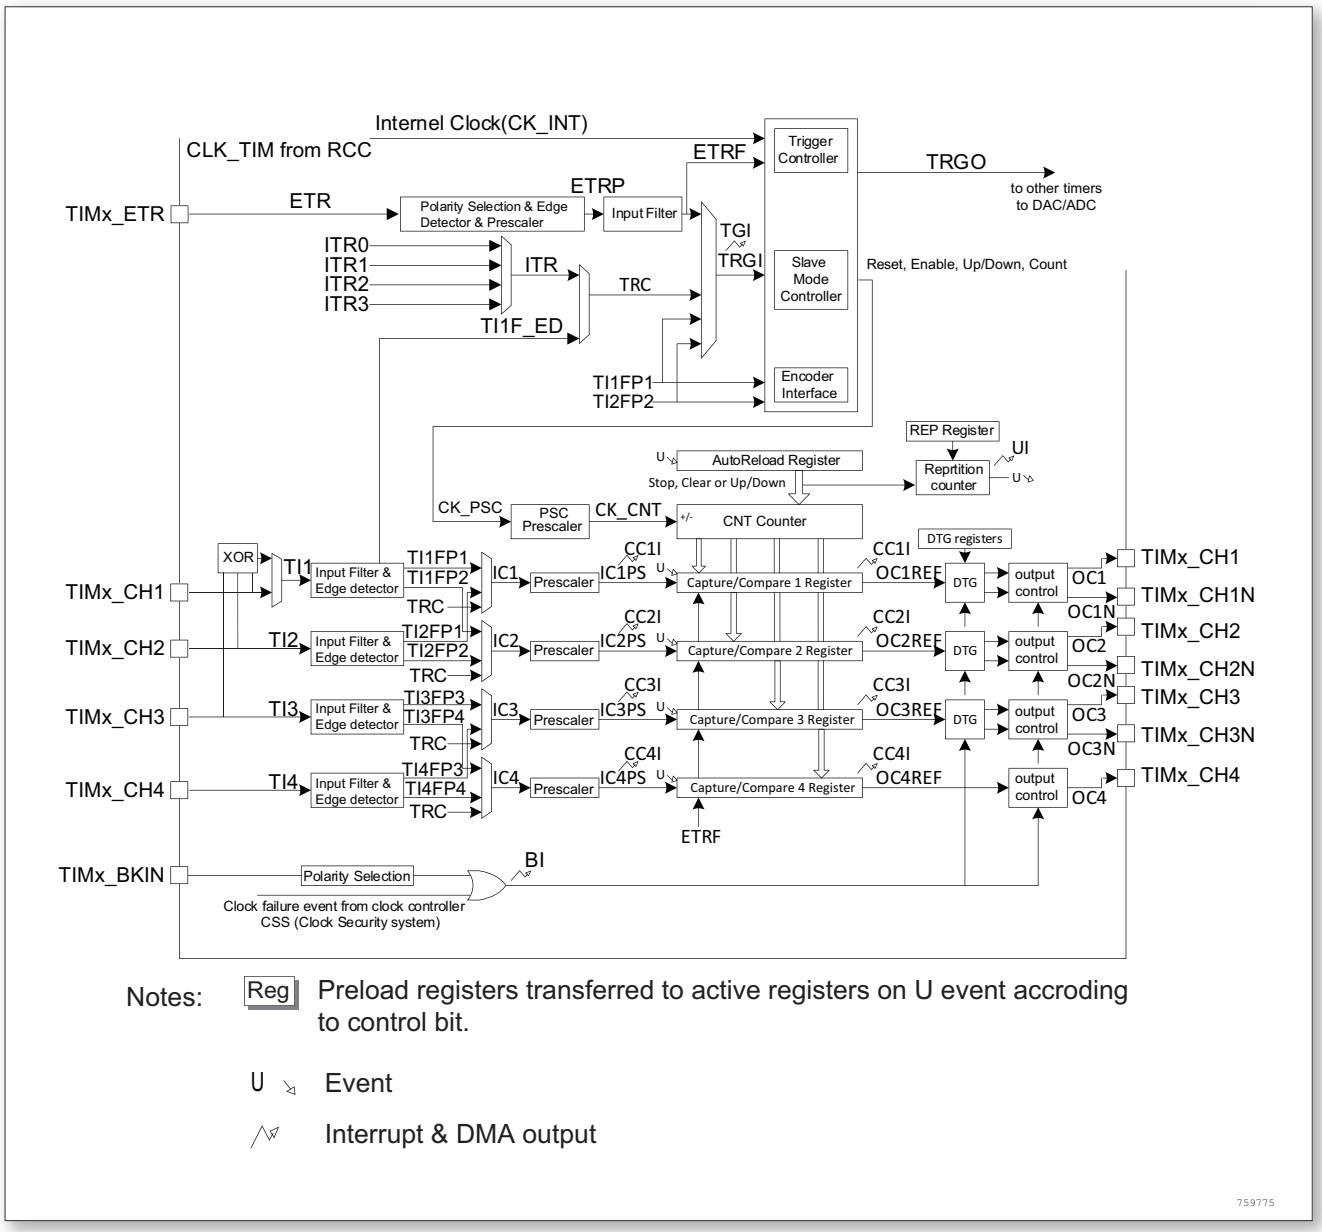

Figure 29. Block Diagram of Advanced-control Timer

11.3 Functional description

11.3.1 Time-base unit

The main block of the programmable advanced-control timer is a 16-bit counter with its related auto-reload register. The counter can count up, down or both up and down. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by

software. This is true even when the counter is running.

The time-base unit includes:

- Counter register (TIMx_CNT)
- Prescaler register (TIMx_PSC)
- Auto-reload register (TIMx_ARR)
- Repetition counter register (TIMx_RCR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter reaches the overflow (or underflow when downcounting) and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in details for each configuration.

The counter is clocked by the prescaler output CK_CNT, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note: The counter starts counting 1 clock cycle after setting the CEN bit in the TIMx_CR register.

Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler factor is taken into account at the next update event.

The following figures give some examples of the counter behavior when the prescaler factor is changed on the fly:

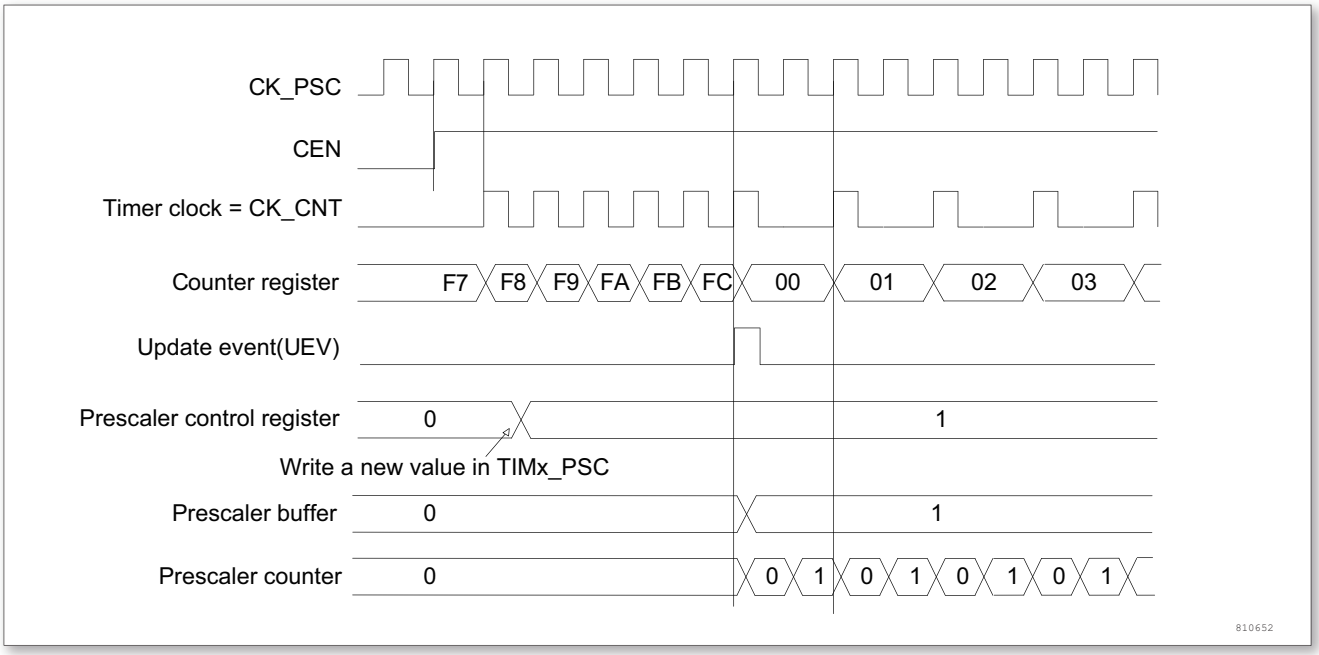

Figure 30. Counter Timing Diagram with Prescaler Division Change from 1 to 2

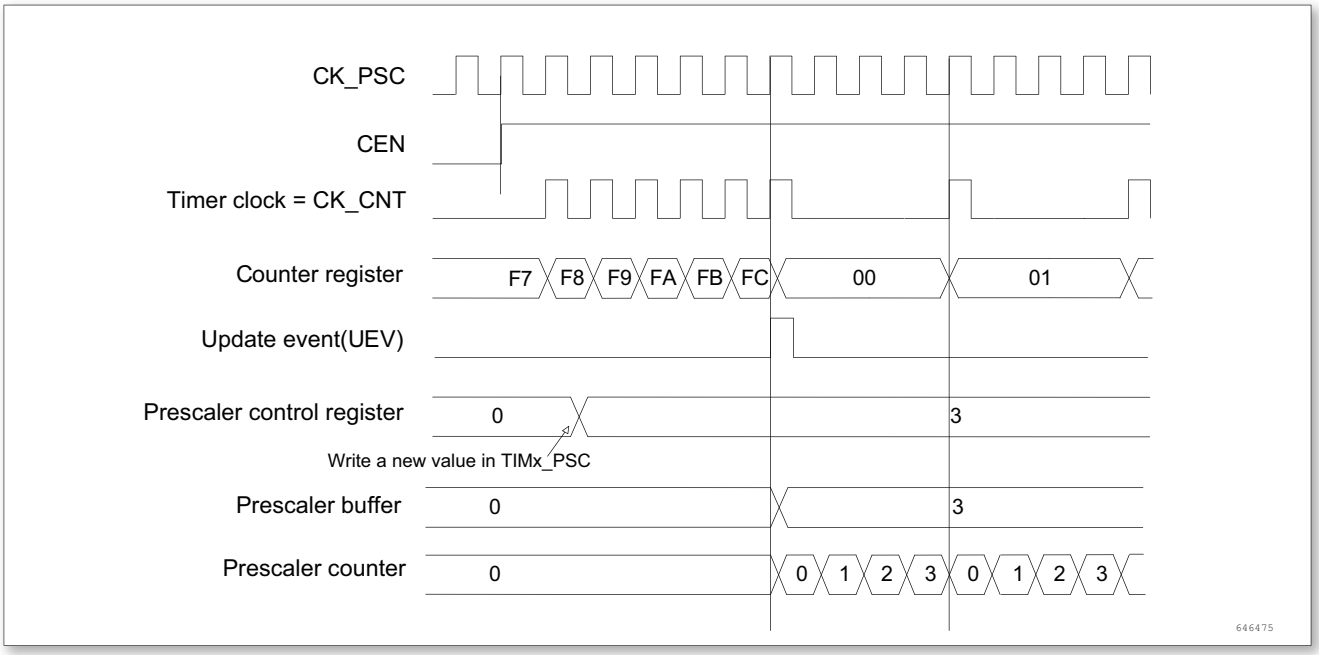

Figure 31. Counter Timing Diagram with Prescaler Division Change from 1 to 4

11.3.2 Counter modes

Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

If the repetition counter is used, the update event (UEV) is generated after upcounting is repeated for the number of times programmed in the repetition counter register (TIMx_RCR). Otherwise, the update event is generated at each counter overflow.

Setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change).

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag bit(UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register.
- The auto-reload shadow register is updated with the preload value (TIMx_ARR).
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR = 0x36.

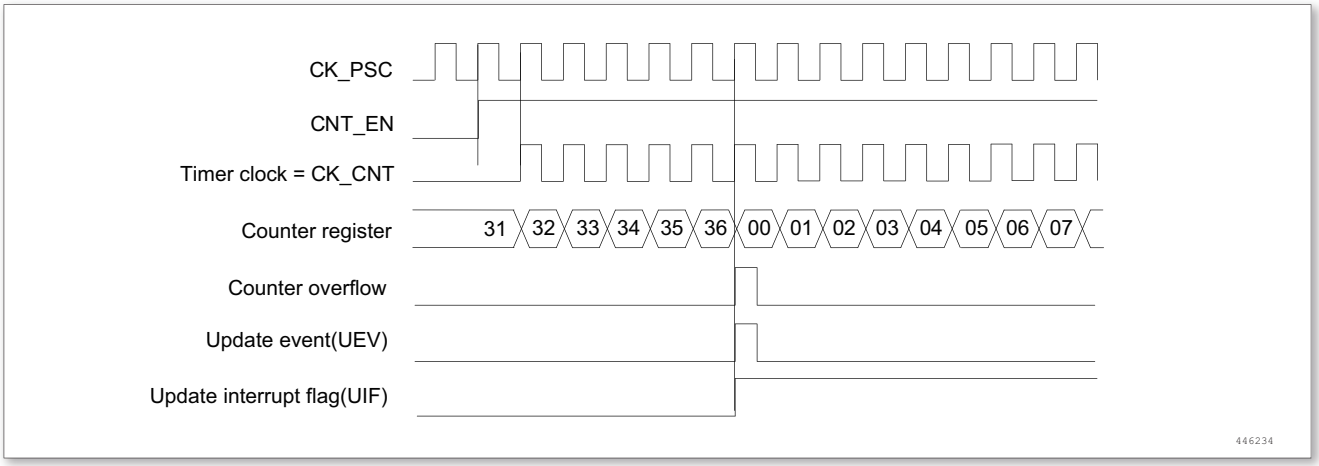

Figure 32. Counter Timing Diagram, Internal Clock Divided by 1

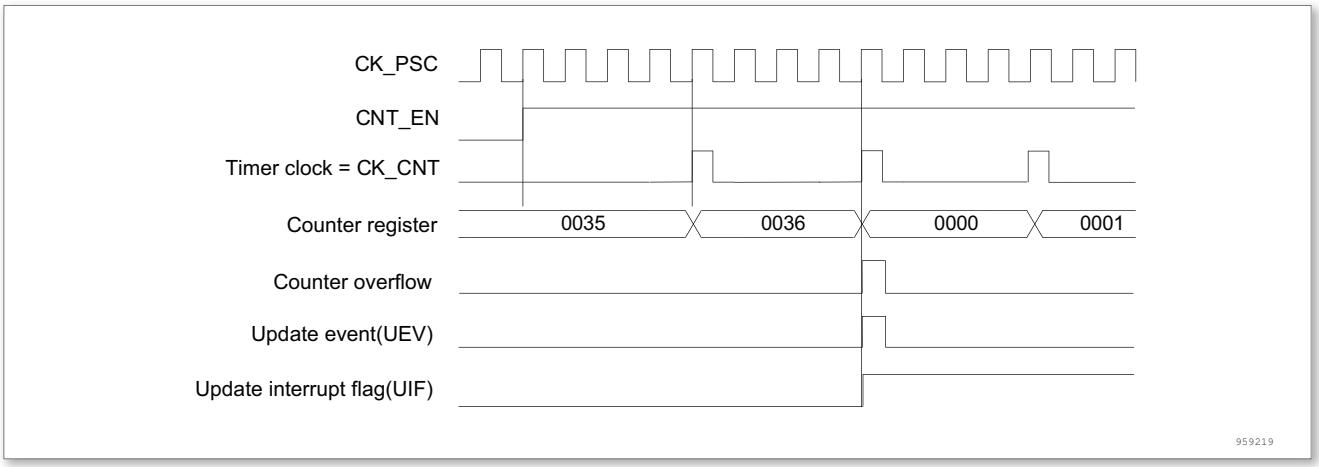

Figure 34. Counter Timing Diagram, Internal Clock Divided by 4

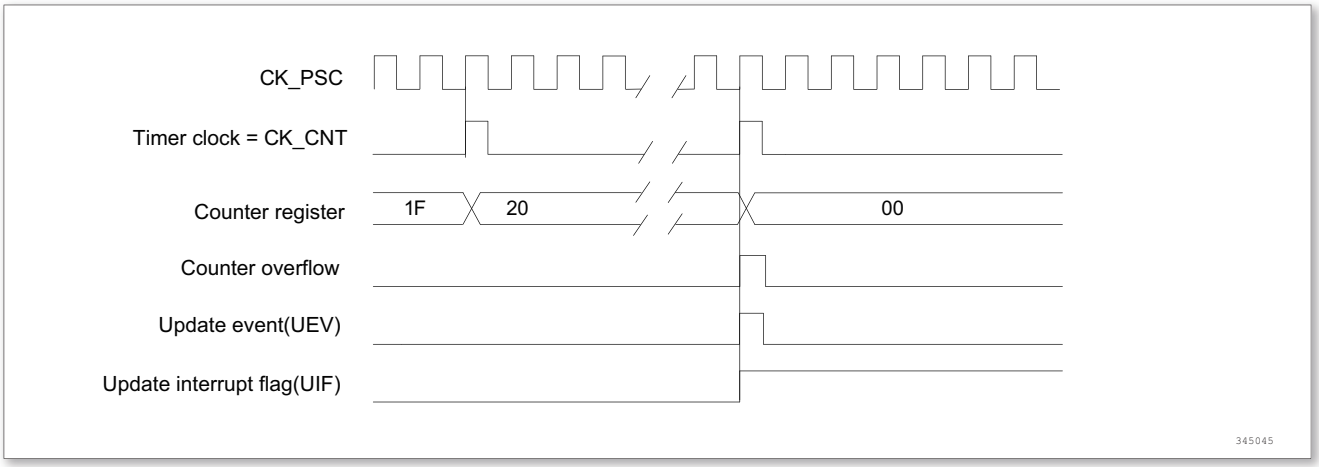

Figure 35. Counter Timing Diagram, Internal Clock Divided by N

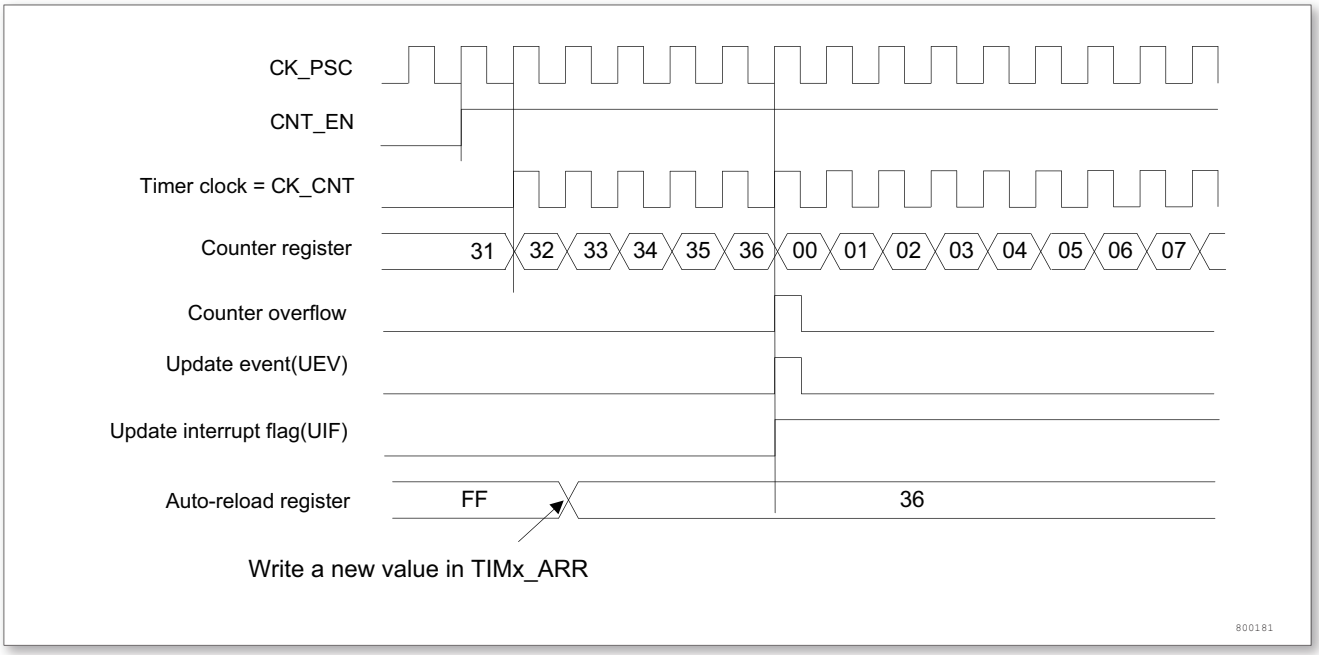

Figure 36. Counter Timing Diagram, Update Event When ARPE = 0 (TiMx_ARR Not Preloaded)

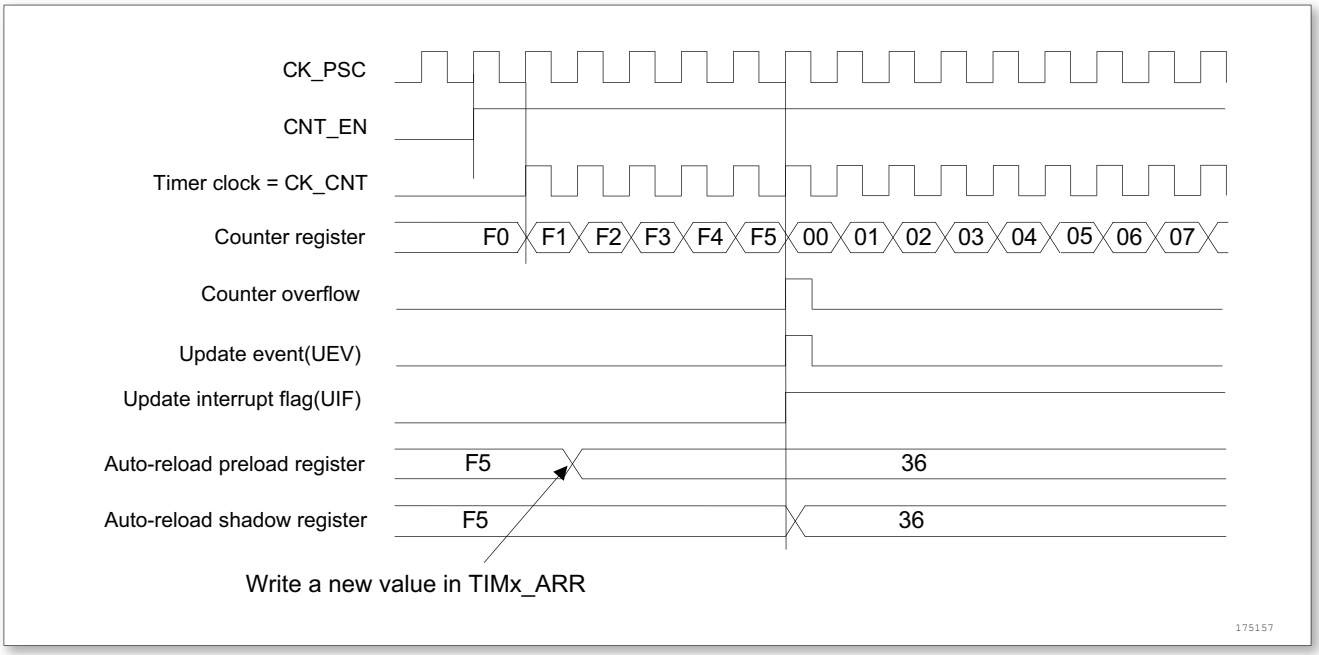

Figure 37. Counter Timing Diagram, Update Event When ARPE = 1 (TiMx_ARR Preloaded)

Downcounting mode

In downcounting mode, the counter counts from the auto-reload value (content of the TIMx_ARR register) down to 0, then restarts from the auto-reload value and generates a counter underflow event.

If the repetition counter is used, the update event (UEV) is generated after downcounting is repeated for the number of times programmed in the repetition counter register plus one (TIMx_RCR). Otherwise, the update event is generated at each counter underflow.

Setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV update event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter restarts from the current auto-reload value, whereas the counter of the prescaler restarts from 0 (but the prescale rate doesn’t change).

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag bit(UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register.
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR

register).

Note: The auto-reload is updated before the counter is reloaded, so that the next period is the expected one.

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR = 0x36.

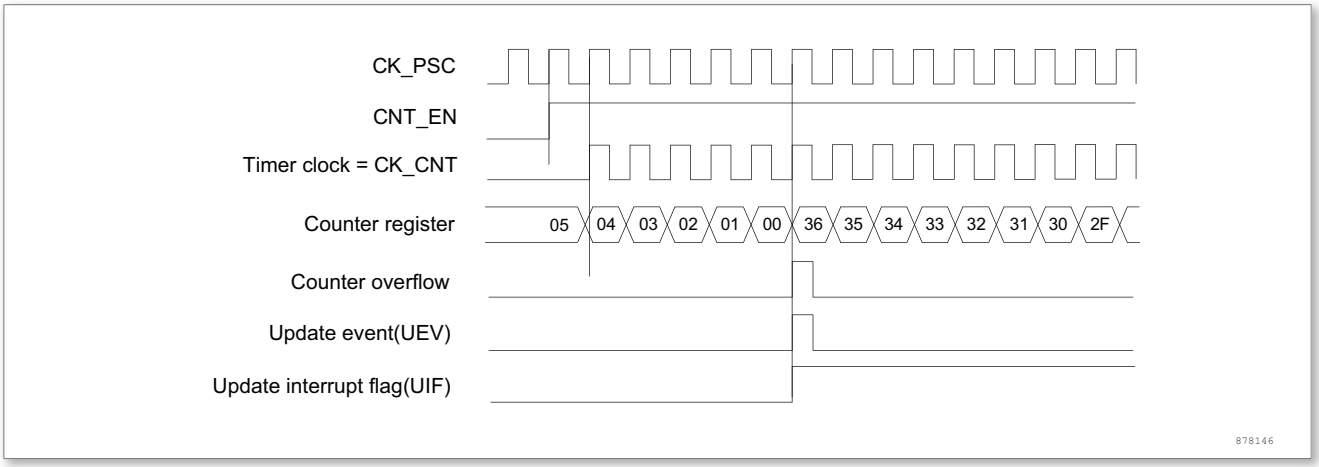

Figure 38. Counter Timing Diagram, Internal Clock Divided by 1

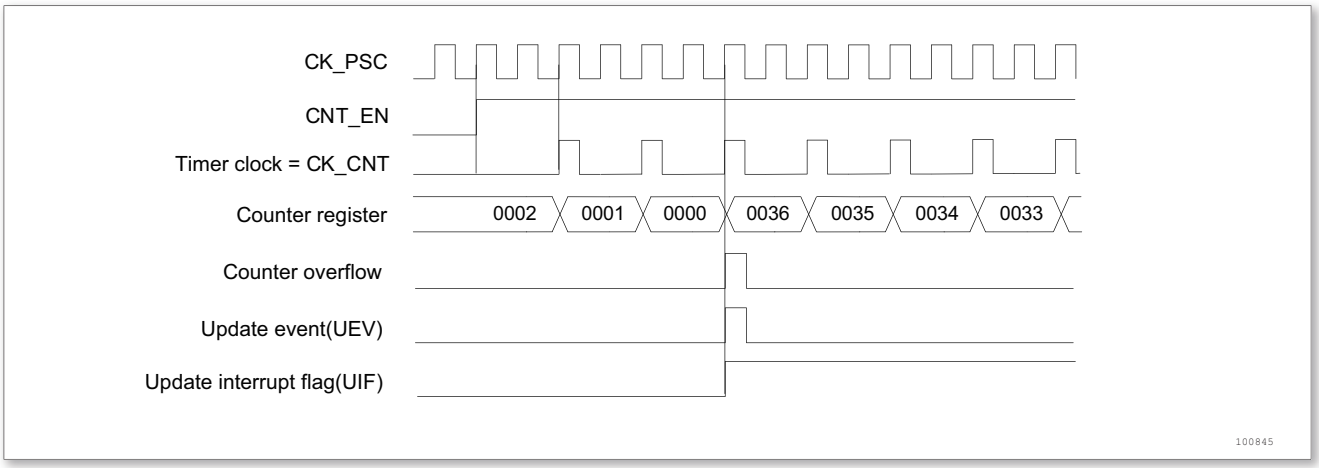

Figure 39. Counter Timing Diagram, Internal Clock Divided by 2

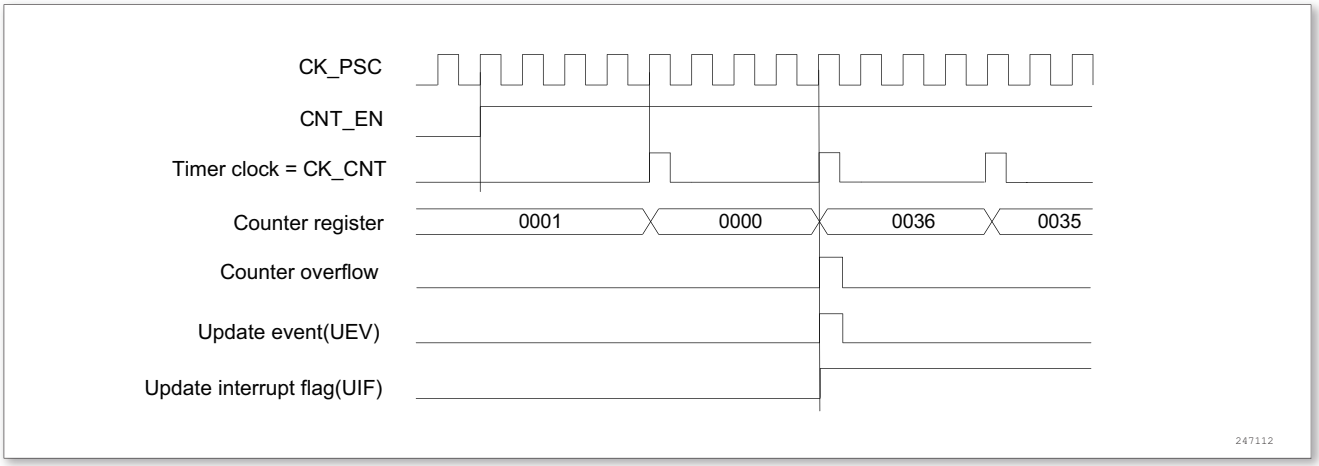

Figure 40. Counter Timing Diagram, Internal Clock Divided by 4

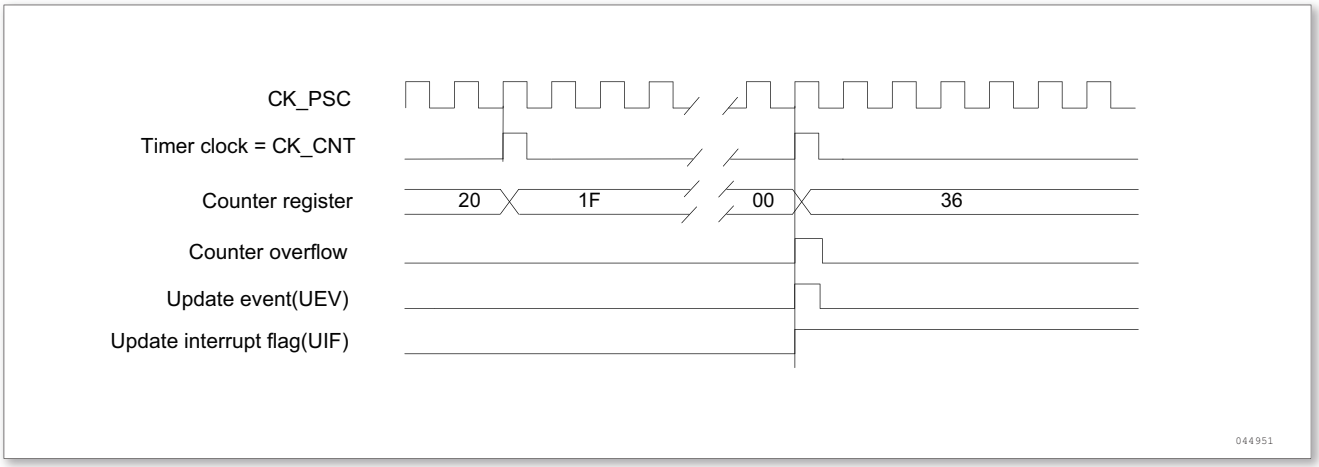

Figure 41. Counter Timing Diagram, Internal Clock Divided by N

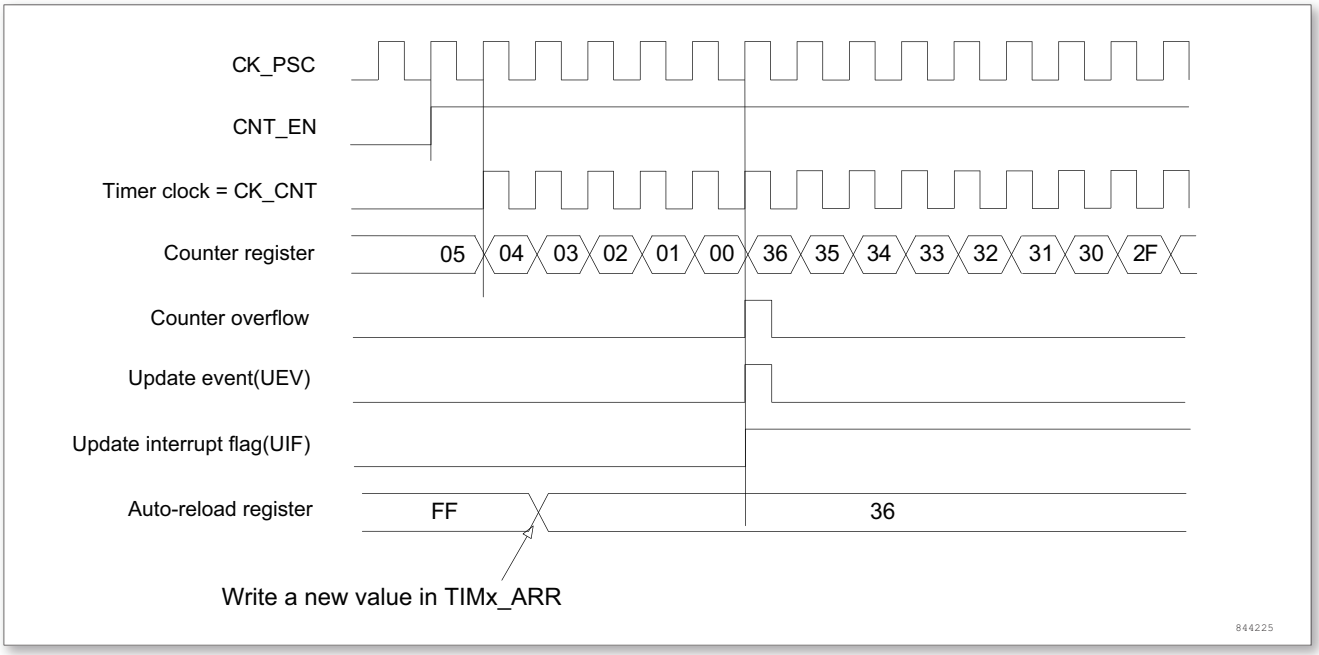

Figure 42. Counter Timing Diagram, Update Event when Repetition Counter is Not Used

Center-aligned mode (Upcounting/Downcounting))

In center-aligned mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register) －1, generates a counter overflow event, then counts from the auto-reload value down to 1 and generates a counter underflow event. Then it restarts counting from 0.

In this mode, the DIR direction bit in the TIMx_CR1 register cannot be written. It is updated by hardware and gives the current direction of the counter.

The update event can be generated at each counter overflow and at each counter underflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) . In this case, the counter restarts counting from 0, so does the counter of the prescaler.

The UEV update event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the

preload registers. Then, no update event occurs until UDIS bit has been written to 0. However, the counter continues counting up and down, based on the current auto-reload value.

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag bit(UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register.
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register).

Note: If the update source is a counter overflow, the auto-reload is updated before the counter is reloaded, so that the next period is the expected one (the counter is loaded with the new value).

The following figures show some examples of the counter behavior for different clock frequencies.

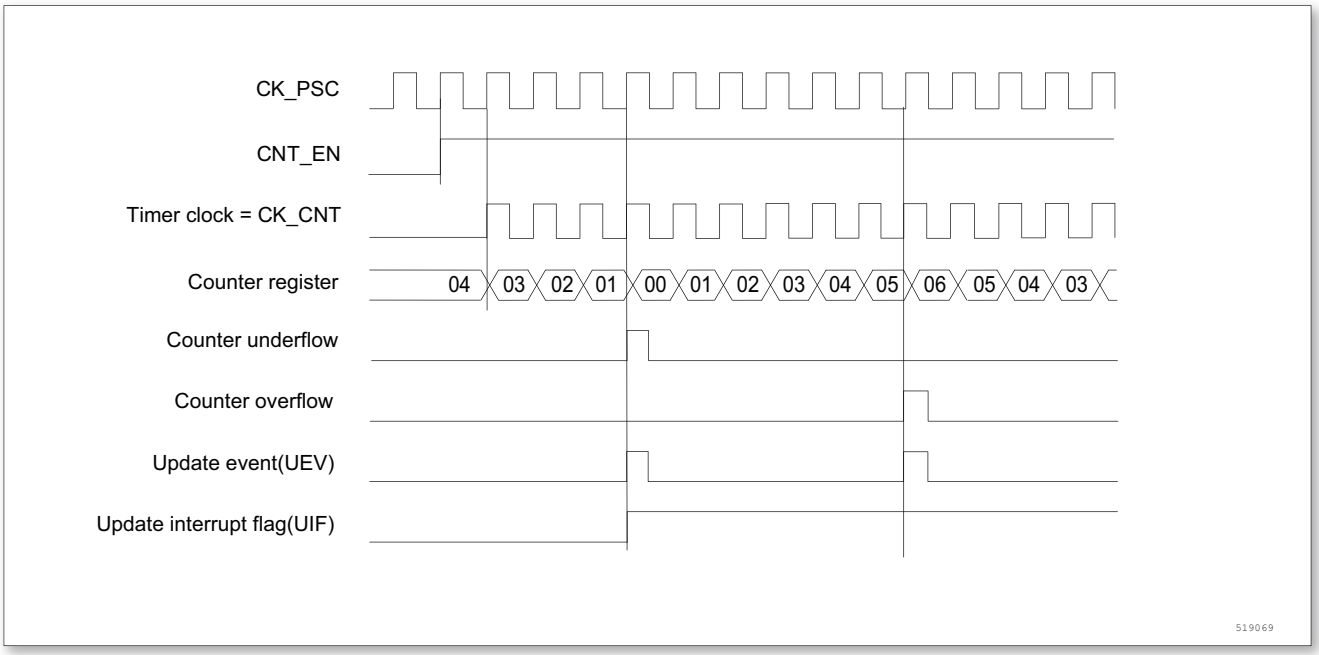

Figure 43. Counter Timing Diagram, Internal Clock Divided by 1, TIMx_ARR = 6

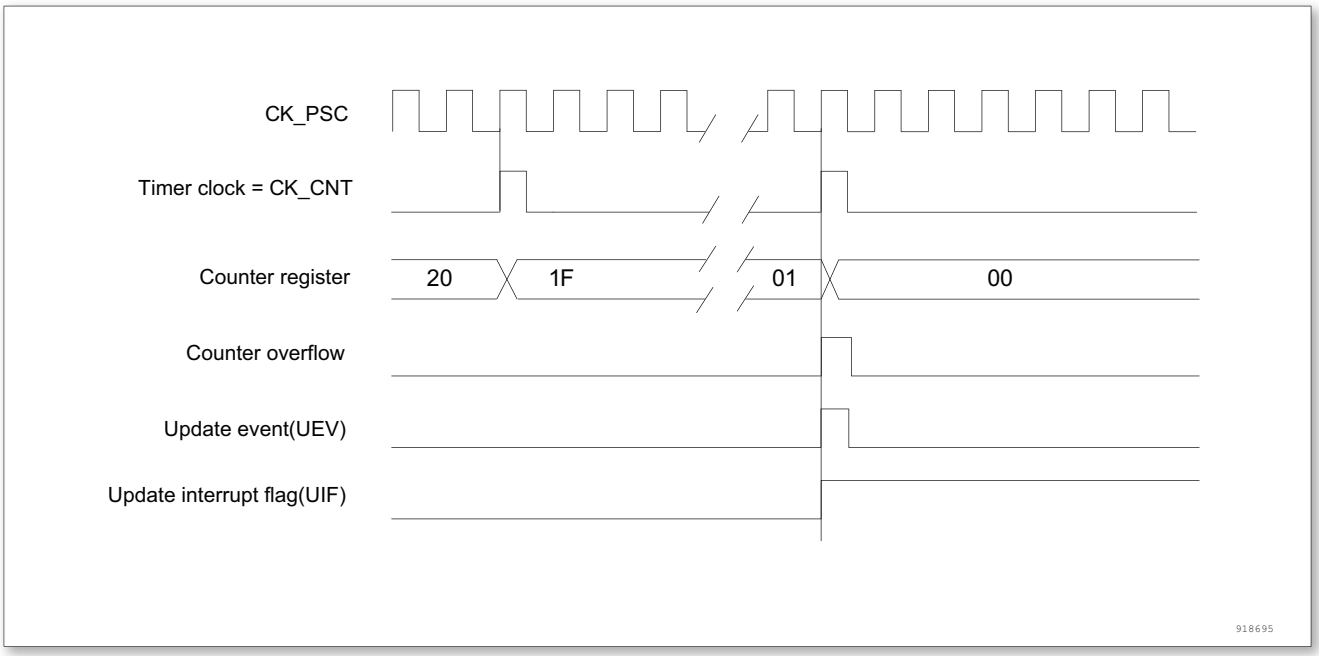

Figure 46. Counter Timing Diagram, Internal Clock Divided by N

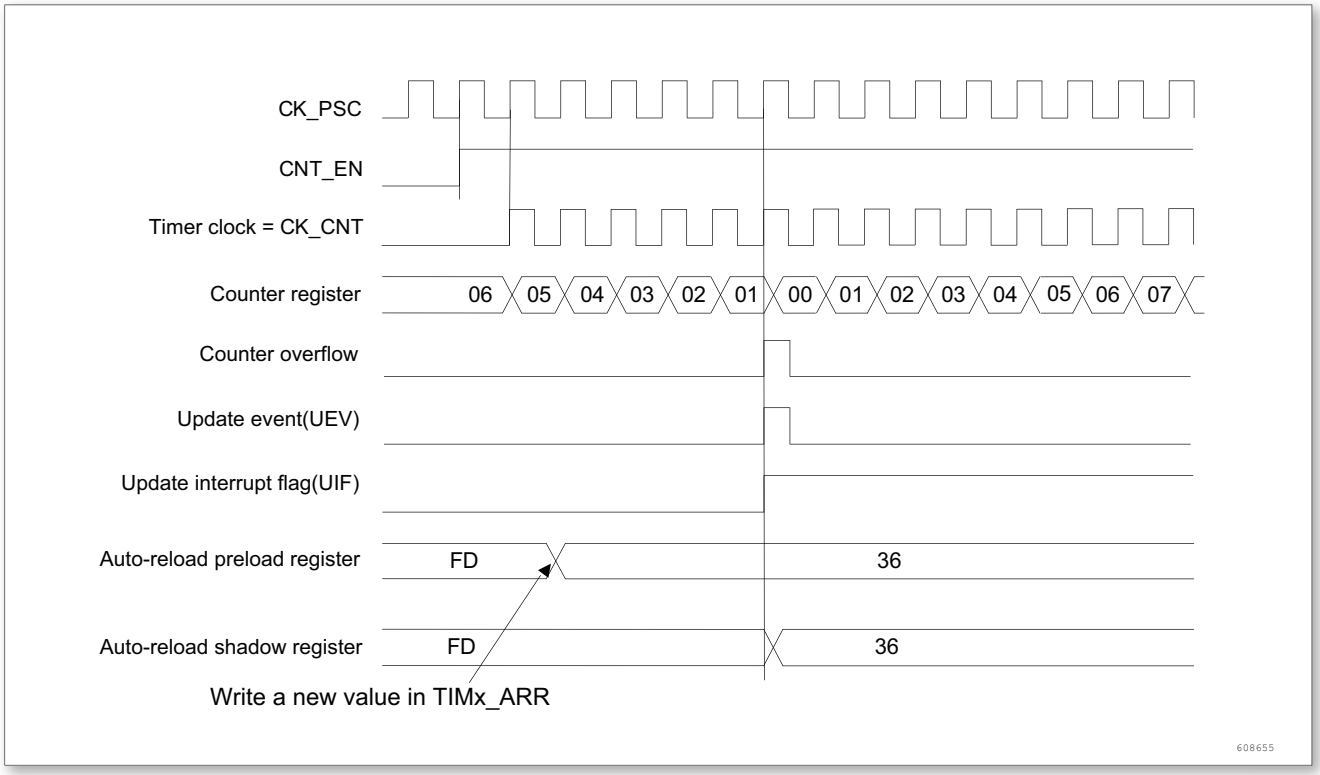

Figure 47. Counter Timing Diagram, Update Event with ARPE = 1(Counter Underflow)

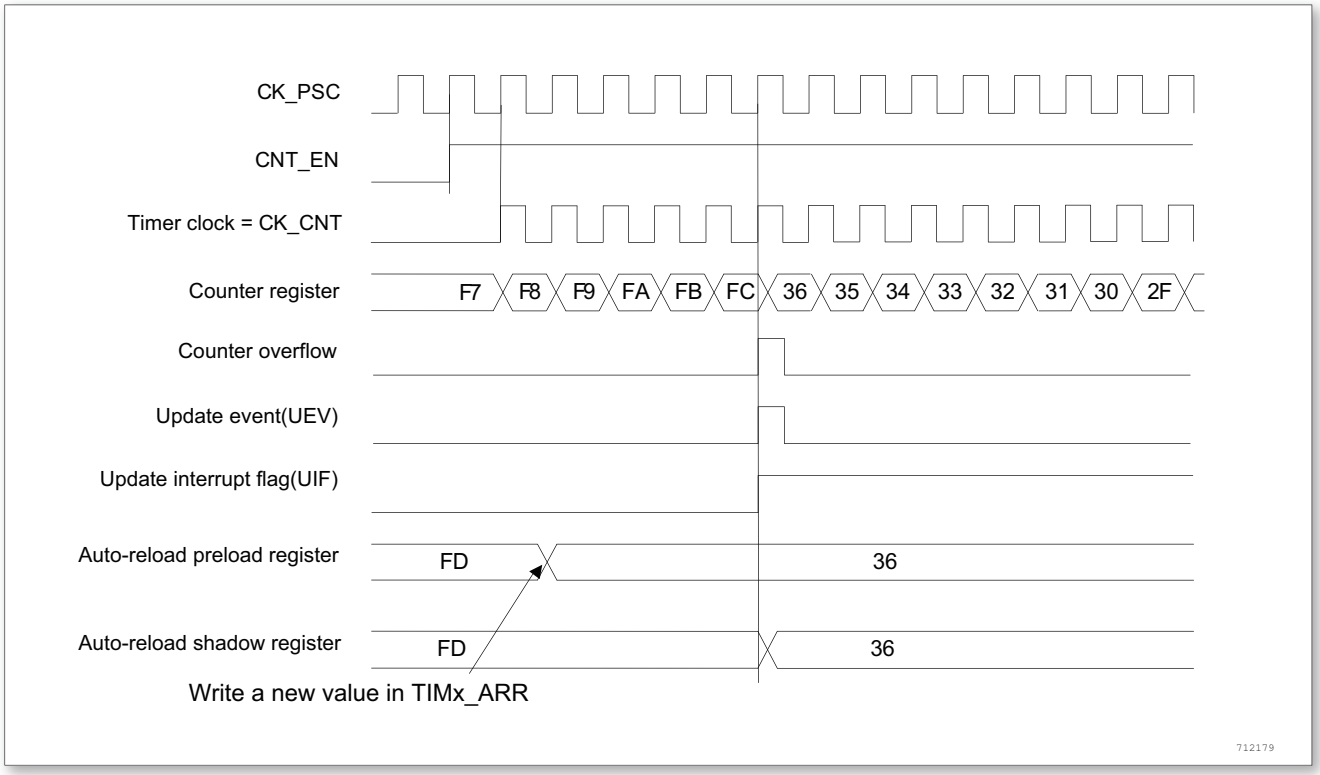

Figure 48. Counter Timing Diagram, Update Event with ARPE = 1(Counter Overflow))

11.3.3 Repetition counter

Time-base unit describes how the update event (UEV) is generated with respect to the counter overflows/underflows. It is actually generated only when the repetition counter has reached zero. This can be useful when generating PWM signals.

This means that data are transferred from the preload registers to the shadow registers (TIMx_ARR auto-reload register, TIMx_PSC prescaler register, but also TIMx_CCRx capture/compare registers in compare mode) every N counter overflows or underflows, where N is the value in the TIMx_RCR repetition counter register.

The repetition counter is decremented:

- At each counter overflow in upcounting mode;
- At each counter underflow in downcounting mode;
- At each counter overflow and at each counter underflow in center-aligned mode. Although this limits the maximum number of repetition to 128 PWM cycles, it makes it possible to update the duty cycle twice per PWM period. When refreshing compare registers only once per PWM period in center-aligned mode, maximum resolution is 2xTck, due to the symmetry of the pattern.

The repetition counter is an auto-reload type; the repetition rate is maintained as defined by the TIMx_RCR register value (refer to Figure 49). When the update event is generated by software (by setting the UG bit in TIMx_EGR register) or by hardware through the slave mode controller, it occurs immediately whatever the value of the repetition counter is and the repetition counter is reloaded with the content of the TIMx_RCR register.

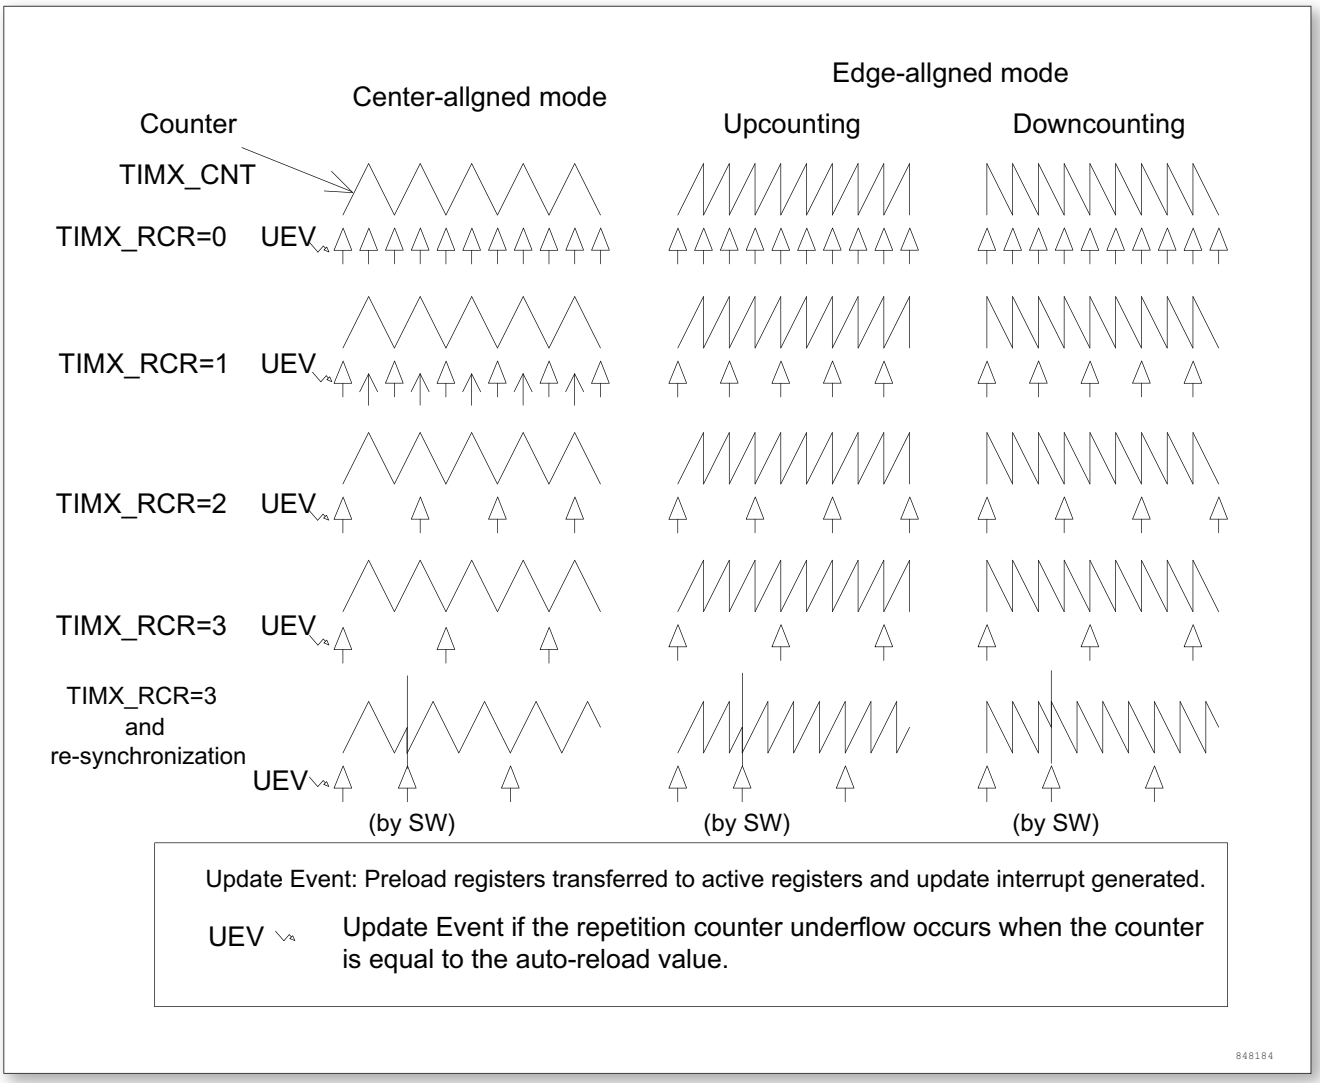

Figure 49. Update Rate Examples Depending on Modes and TIMx_RCR Register Settings

11.3.4 Clock selection

The counter clock can be provided by the following clock sources:

- Internal clock (CK_INT).
- External clock mode1: external input pin (TIx).
- External clock mode2: external trigger input (ETR).
- Internal trigger inputs (ITRx): using one timer as prescaler for another timer, for example, the user can configure Timer 1 to act as a prescaler for Timer 2.

Internal clock (CK_INT)

If the slave mode controller is disabled (SMS=000), then the CEN, DIR (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock CK_INT.

The following figure shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

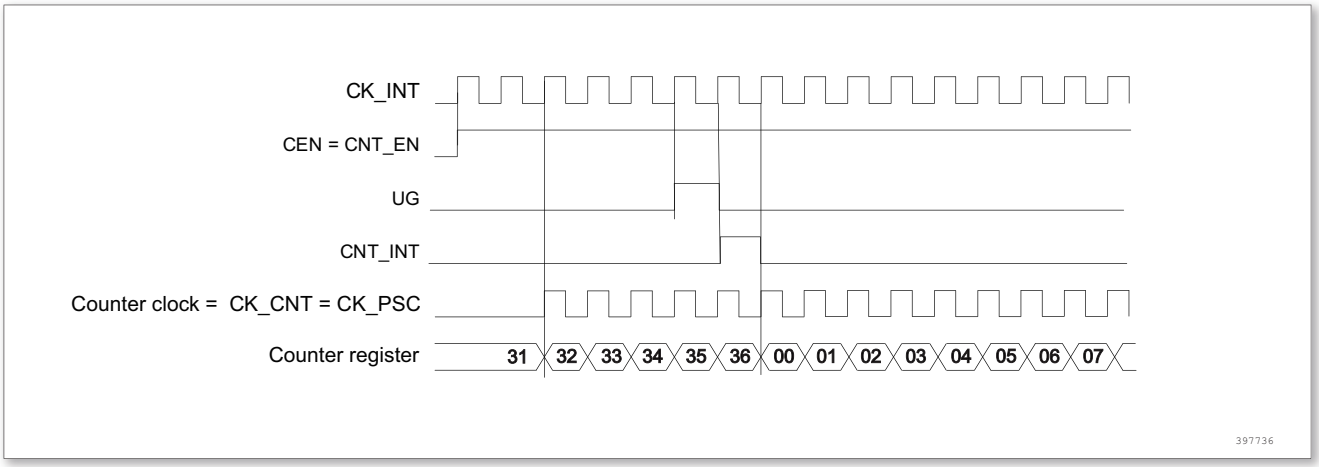

Figure 50. Control Circuit in Normal Mode, Internal Clock Divided By 1

External clock source mode 1

This mode is selected when SMS=111 in the TIMx_SMCR register. The counter can count at each rising or falling edge on a selected input.

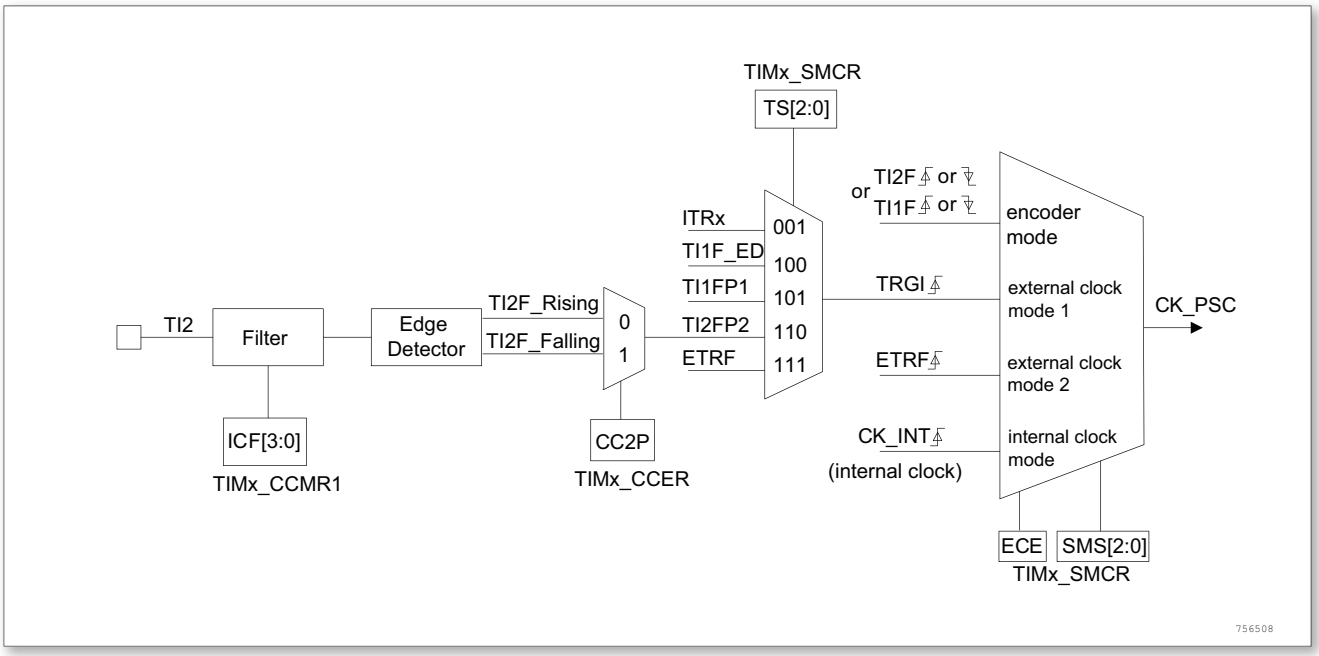

Figure 51. TI2 External Clock Connection Example

For example, to configure the upcounter to count in response to a rising edge on the TI2 input, use the following procedure:

1. Configure channel 2 to detect rising edges on the TI2 input by writing CC2S = ‘01’ in the TIMx_CCMR1 register.
2. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx_CCMR1 register (if no filter is needed, keep IC2F=0000).
3. Select rising edge polarity by writing CC2P=0 in the TIMx_CCER register.
4. Select the timer in external clock mode 1 by writing SMS=111 in the TIMx_SMCR register.
5. Select TI2 as the trigger input source by writing TS=110 in the TIMx_SMCR register.

6. Enable the counter by writing CEN=1 in the TIMx_CR1 register.

Note: The capture prescaler is not used for triggering, so the user does not need to configure it. When a rising edge occurs on TI2, the counter counts once and the TIF flag is set. The delay between the rising edge on TI2 and the actual clock of the counter is due to the resynchronization circuit on TI2 input.

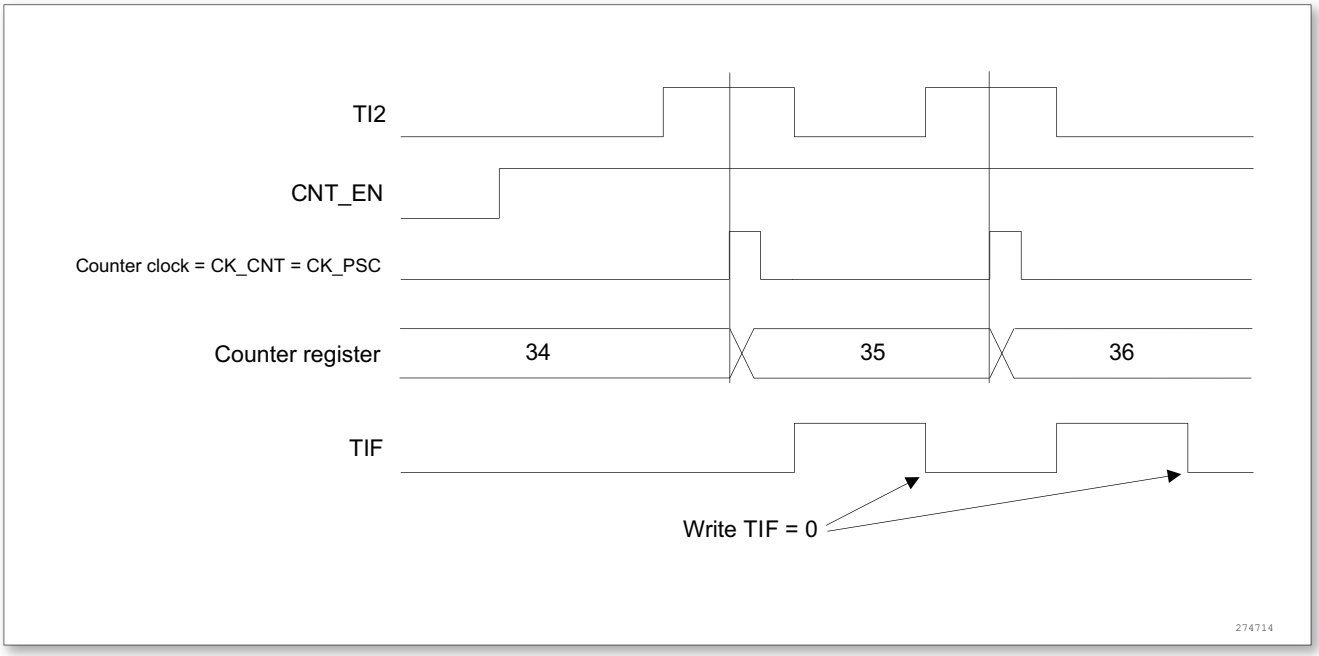

Figure 52. Control Circuit in External Clock Mode 1

External clock source mode 2

This mode is selected by writing ECE = 1 in the TIMx_SMCR register.

The counter can count at each rising or falling edge on the external trigger input ETR.

The following figure gives an overview of the external trigger input block.

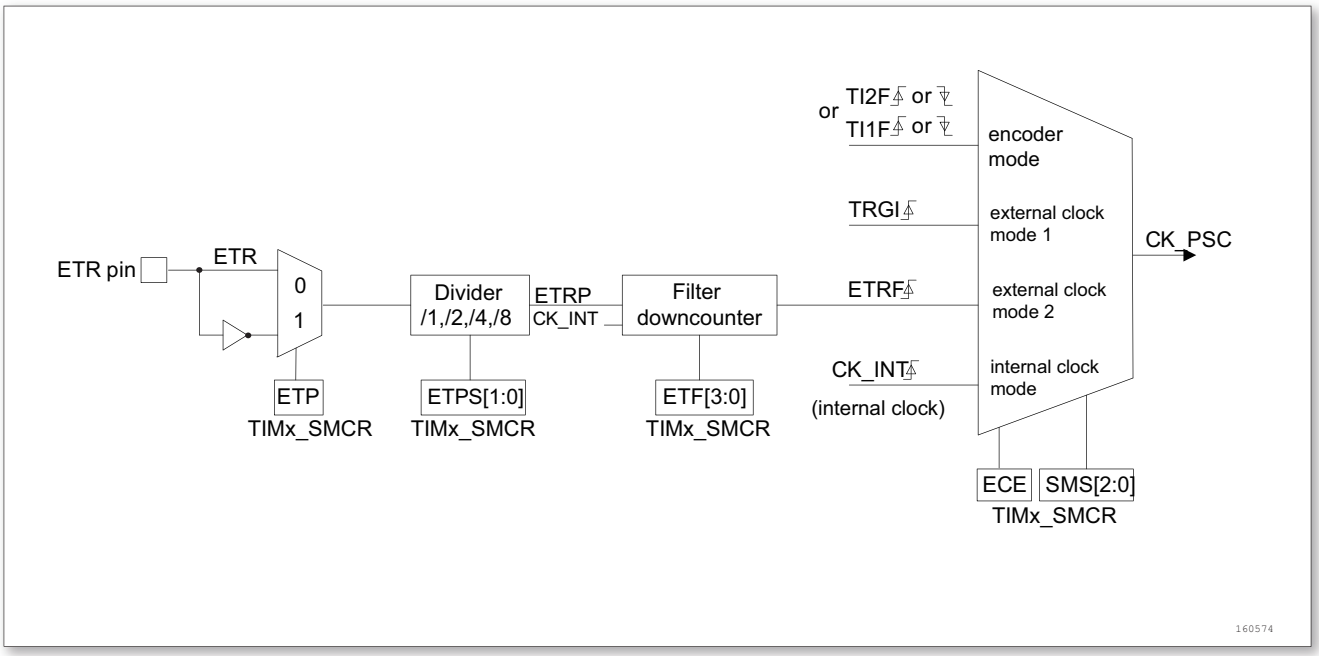

Figure 53. External Trigger Input Block

For example, to configure the upcounter to count once each 2 rising edges on ETR, use the following procedure:

- As no filter is needed in this example, write ETF [3:0]=0000 in the TIMx_SMCR register.
- Set the prescaler by writing ETPS [1:0]=01 in the TIMx_SMCR register.
- Select rising edge detection on the ETR pin by writing ETP=0 in the TIMx_SMCR register.
- Enable external clock mode 2 by writing ECE=1 in the TIMx_SMCR register.
- Enable the counter by writing CEN=1 in the TIMx_CR1 register.

The counter counts once each 2 ETR rising edges.

The delay between the rising edge on ETR and the actual clock of the counter is due to the resynchronization circuit on the ETRP signal.

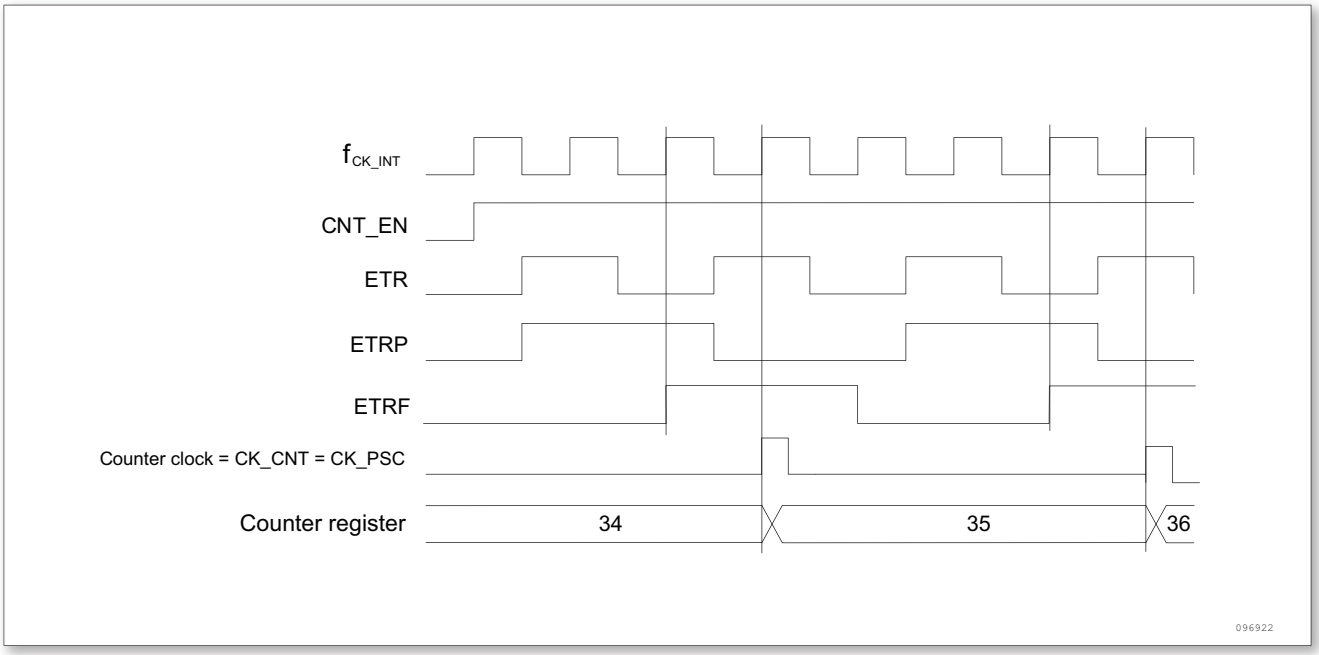

Figure 54. Control Circuit in External Clock Mode 2

11.3.5 Capture/compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), including an input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control).

Figure 55 to Figure 58 give an overview of one Capture/Compare channel.

The input stage samples the corresponding TIx input to generate a filtered signal TIxF. Then, an edge detector with polarity selection generates a signal (TIxFPx) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).

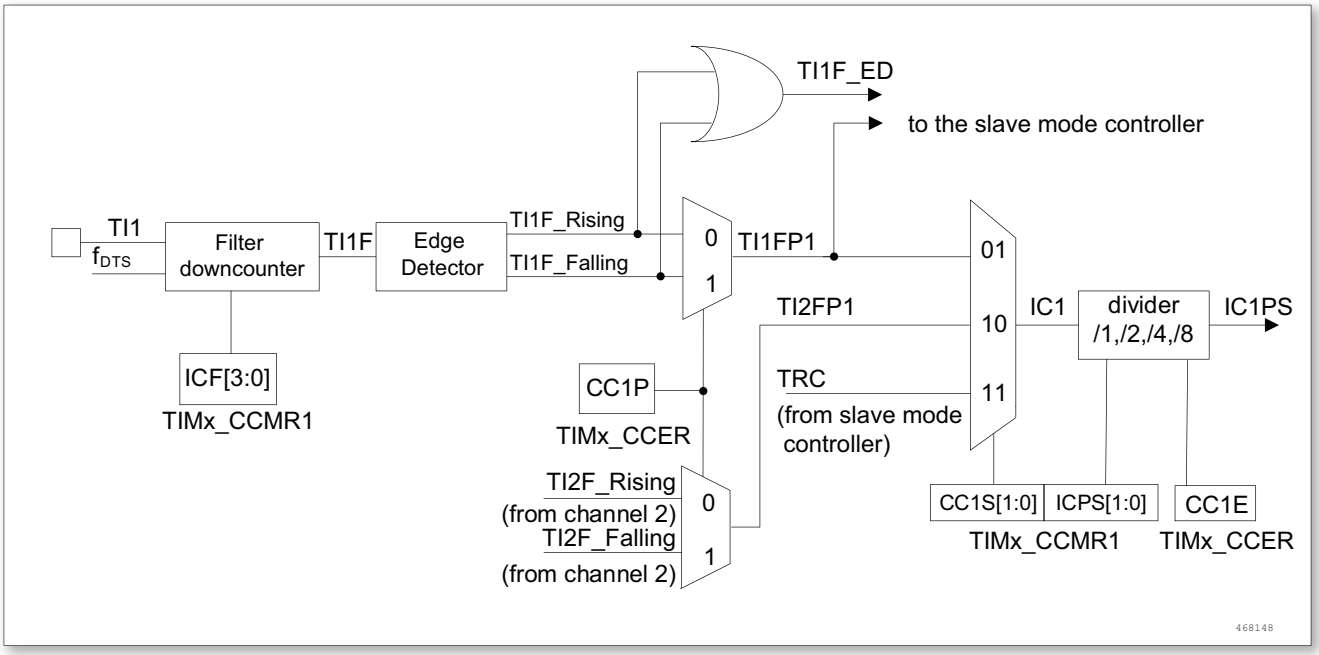

Figure 55. Capture/Compare Channel (Example: Channel 1 Input Stage)

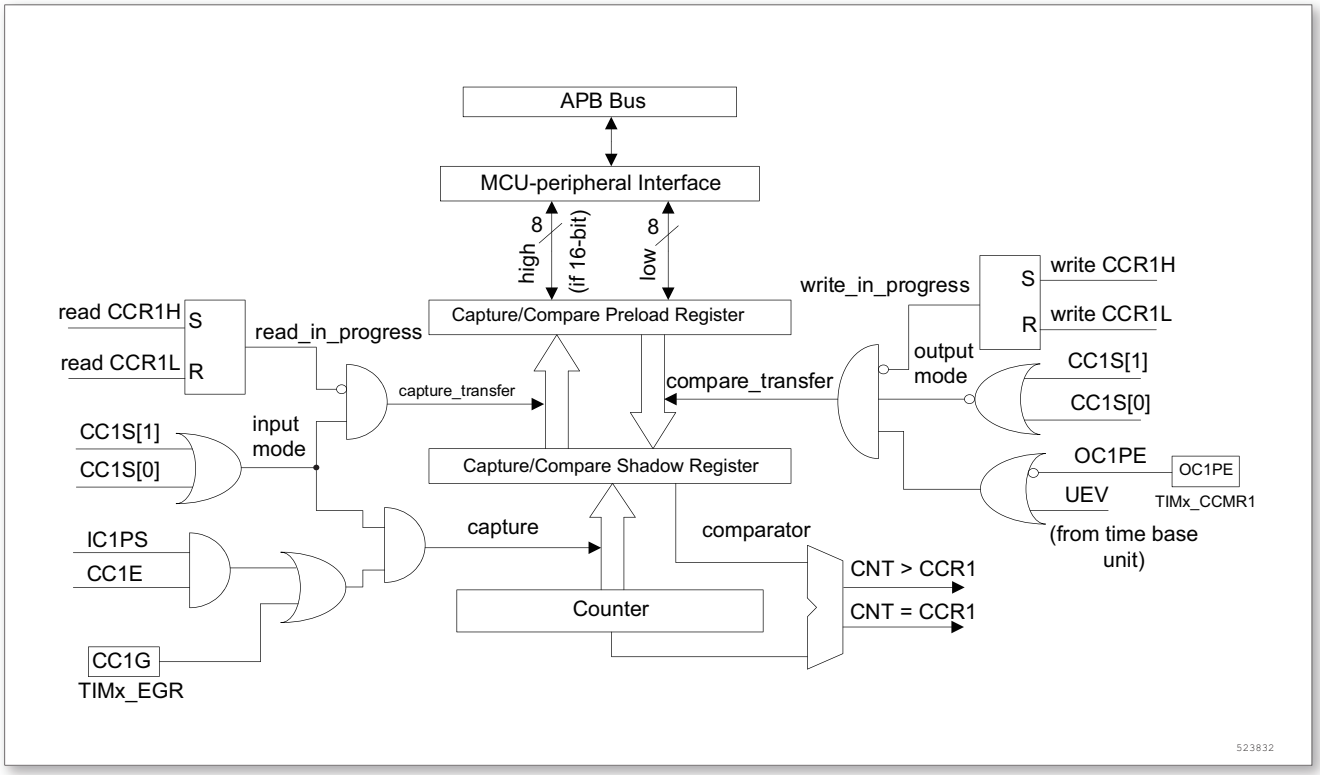

Figure 56. Capture/Compare Channel 1 Main Circuit

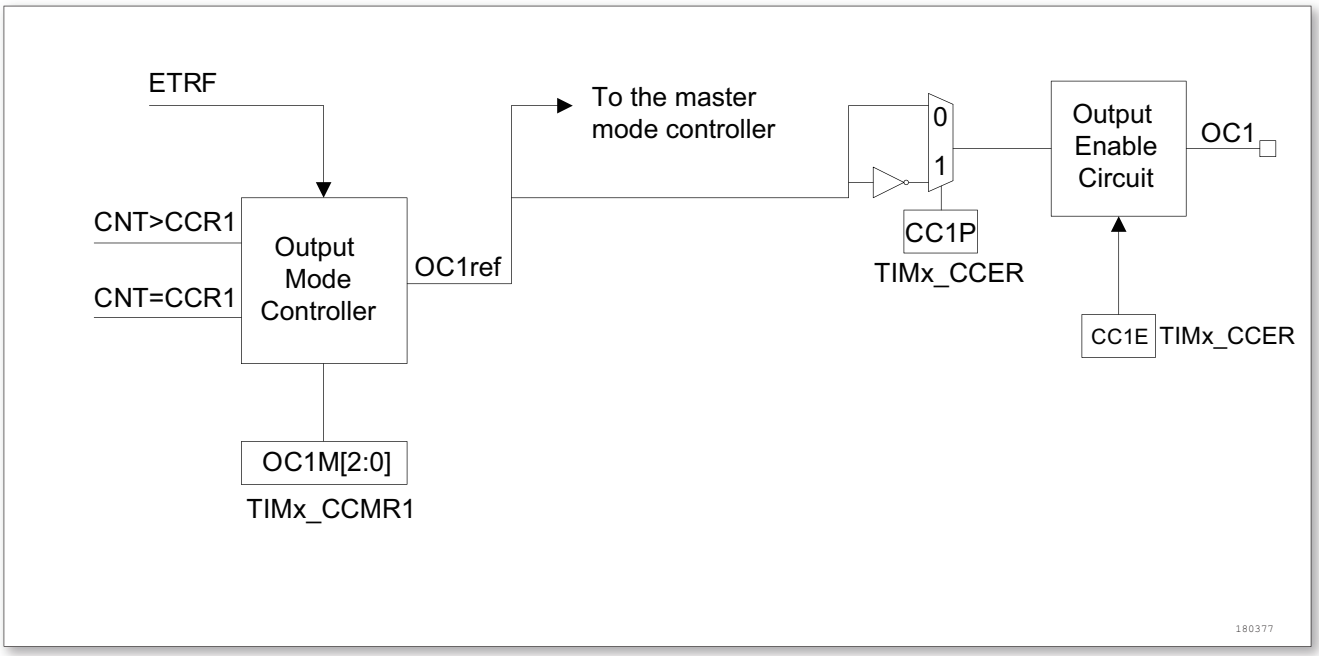

Figure 57. Output stage of Capture/Compare Channel (Channels 1 to 3)

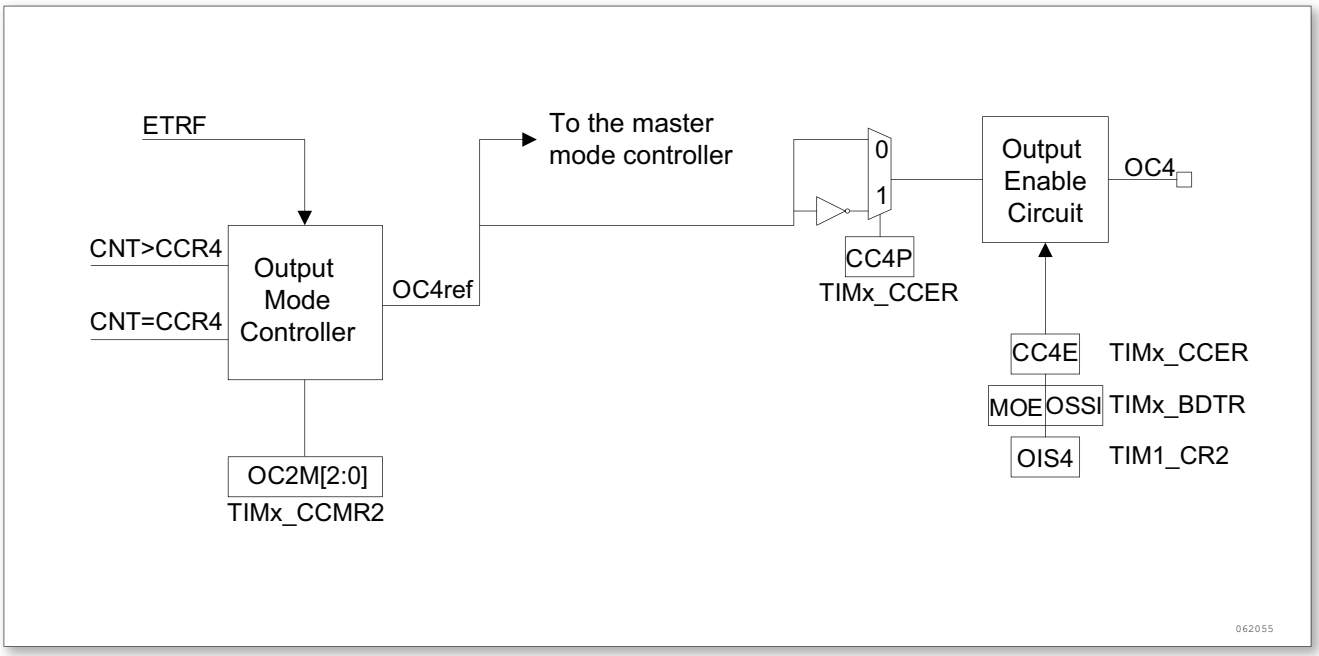

Figure 58. Output stage of Capture/Compare Channel (Channel 4)

The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register. In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

11.3.6 Input capture mode

In Input capture mode, the Capture/Compare Registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When

a capture occurs, the corresponding CCxIF flag (TIMx_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxOF (TIMx_SR register) is set. CCxIF can be cleared by software by writing it to '0' or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when written to '0'.

The following example shows how to capture the counter value in TIMx_CCR1 when TI1 input rises. To do this, use the following procedure:

- Select the active input: TIMx_CCR1 must be linked to the TI1 input, so write the CC1S bits to 01 in the TIMx_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIMx_CCR1 register becomes read-only.
- Program the needed input filter duration with respect to the signal connected to the timer (by programming ICxF bits in the TIMx_CCMRx register if the input is a TIx input). Let's imagine that, when toggling, the input signal is not stable during at most five internal clock cycles. We must program a filter duration longer than these five clock cycles. We can validate a transition on TI1 when 8 consecutive samples with the new level have been detected (sampled at fDTS frequency). Then write IC1F bits to 0011 in the TIMx_CCMR1 register.
- Select the edge of the active transition on the TI1 channel by writing CC1P bit to 0 in the TIMx_CCER register (rising edge in this case).
- Configure the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to '00' in the TIMx_CCMR1 register).
- Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx_CCER register to '1'.
- If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx_DIER register.

When an input capture occurs:

- TIMx_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the over-capture flag. This is to avoid missing an overcapture which could happen after reading the flag and before reading the data.

Note: IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx_EGR register.

11.3.7 PWM input mode

This mode is a particular case of input capture mode. The procedure is the same except:

- Two ICx signals are mapped on the same TIx input.
- These 2 ICx signals are active on edges with opposite polarity.

- One of the two TIxFP signals is selected as trigger input and the slave mode controller is configured in reset mode. For example, user can measure the period (in TIMx_CCR1 register) and the duty cycle (in TIMx_CCR2 register) of the PWM applied on TI1 using the following procedure (depending on CK_INT frequency and prescaler value):
- Select the active input for TIMx_CCR1: write the CC1S bits to 01 in the TIMx_CCMR1 register (TI1 selected).
- Select the active polarity for TI1FP1 (used both for capture in TIMx_CCR1 and counter clear): write the CC1P bit to '0' (active on rising edge).
- Select the active input for TIMx_CCR2: write the CC2S bits to 10 in the TIMx_CCMR1 register (TI1 selected).
- Select the active polarity for TI1FP2 (used for capture in TIMx_CCR2): write the CC2P bit to '1' (active on falling edge).
- Select the valid trigger input: write the TS bits to 101 in the TIMx_SMCR register (TI1FP1 selected).
- Configure the slave mode controller in reset mode: write the SMS bits to 100 in the TIMx_SMCR register.
- Enable the captures: write the CC1E and CC2E bits to '1' in the TIMx_CCER register.

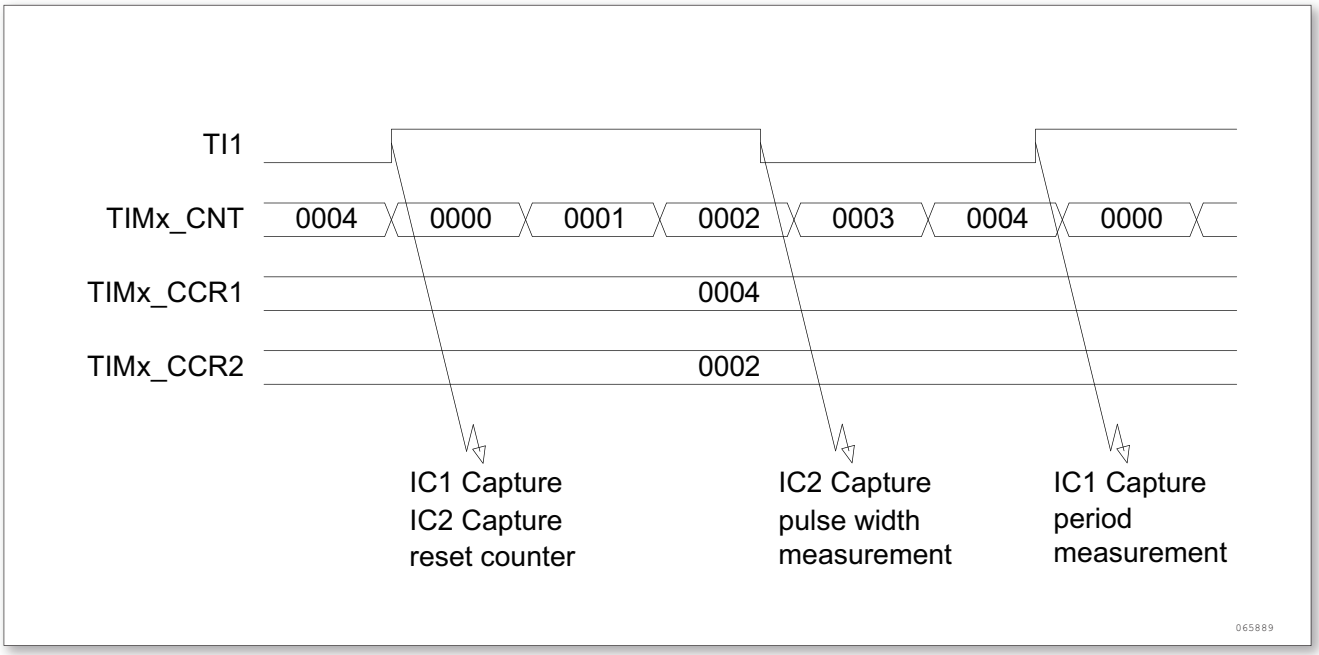

Figure 59. PWM Input Mode Timing

The PWM input mode can be used only with the TIMx_CH1/TIMx_CH2 signals due to the fact that only TI1FP1 and TI2FP2 are connected to the slave mode controller.

11.3.8 Forced output mode

In output mode (CCxS bits = 00 in the TIMx_CCMRx register), each output compare signal (OCxREF and then OCx/OCxN) can be forced to active or inactive level directly by software, being independent of any comparison between the output compare register and the counter.

To force an output compare signal (OCXREF/OCx) to its active level, the user just needs to

write 101 in the OCxM bits in the corresponding TIMx_CCMRx register. Thus OCXREF is forced high (OCxREF is always active high) and OCx get opposite value to CCxP polarity bit.

For example: CCxP=0 (OCx active high) => OCx is forced to high level.

The OCxREF signal can be forced low by writing the OCxM bits to 100 in the TIMx_CCMRx register.

Anyway, in this mode, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the output compare mode section below.

11.3.9 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP bit in the TIMx_CCER register). The output pin can keep its level (OCXM=000), be set active (OCxM=001), be set inactive (OCxM=010) or can toggle (OCxM=011) on match.
- Sets a flag bit in the interrupt status register (CCxIF bit in the TIMx_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCXIE bit in the TIMx_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx_DIER register, CCDS bit in the TIMx_CR2 register for the DMA request selection).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

In output compare mode, the update event UEV has no effect on OCxREF and OCx output.

The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One Pulse mode)

Procedure:

- Select the counter clock (internal, external, prescaler).
- Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
- Set the CCxIE bit if an interrupt request is to be generated.
- Select the output mode. For example:
  - Write OCxM = 011 to toggle OCx output pin when CNT matches with CCRx
  - Write OCxPE = 0 to disable preload register
  - Write CCxP = 0 to select active high polarity
  - Write CCxE = 1 to enable the output
- Enable the counter by setting the CEN bit in the TIMx_CR1 register.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE=’0’, otherwise

TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in the following figure.

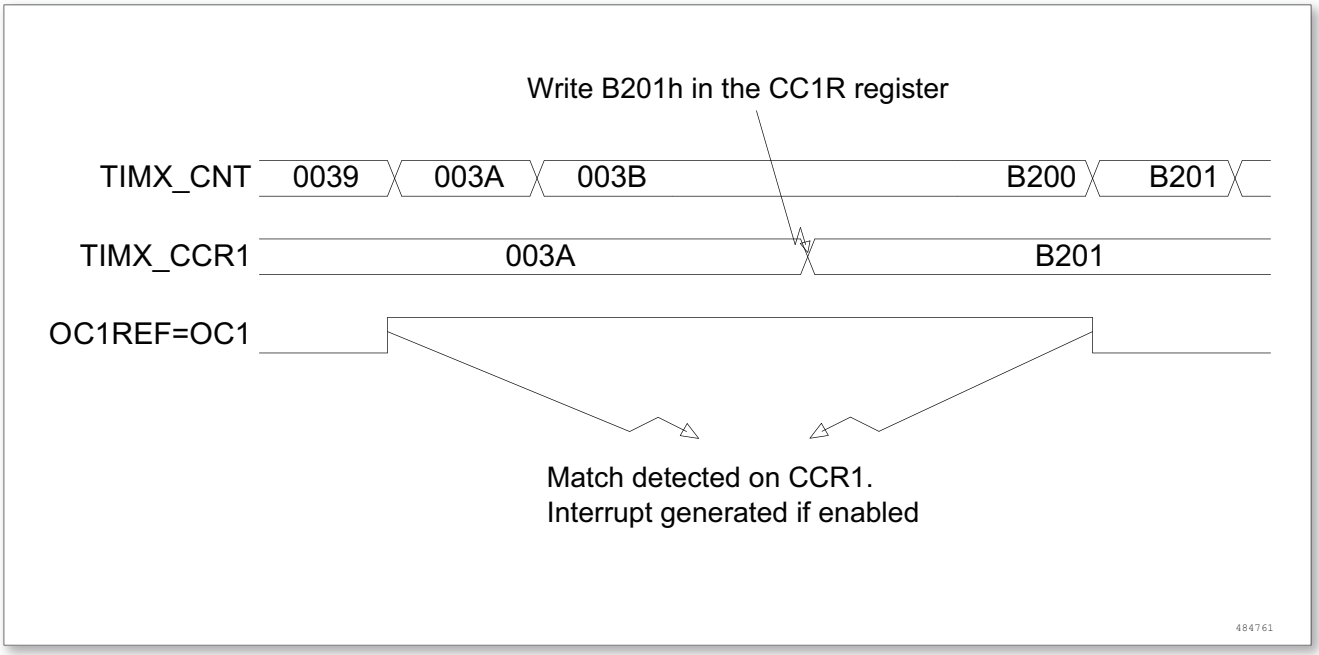

Figure 60. Output Compare Mode, Toggle on OC1

11.3.10 PWM mode

Pulse Width Modulation mode allows generating a signal with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per OCx output) by writing ‘110’ (PWM mode 1) or ‘111’ (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, the user must initialize all the registers by setting the UG bit in the TIMx_EGR register.

OCx polarity is software programmable using the CCxP bit in the TIMx_CCER register. It can be programmed as active high or active low. OCx output is enabled by a combination of the CCxE, CCxNE, MOE, OSSI and OSSR bits (TIMx_CCER and TIMx_BDTR registers). Refer to the TIMx_CCER register for more details.

In PWM mode (1 or 2), TIMx_CNT and TIMx_CCRx are always compared to determine whether TIMx_CCRx ≤TIMx_CNT or TIMx_CNT ≤TIMx_CCRx (depending on the direction of the counter).

The timer is able to generate PWM in edge-aligned mode or center-aligned mode depending on the CMS bits in the TIMx_CR1 register.

PWM edge-aligned mode

Upcounting configuration

Upcounting is active when the DIR bit in the TIMx_CR1 register is low. Refer to section 11.3.2.

In the following example, we consider PWM mode 1. The reference PWM signal OCxREF is high as long as TIMx_CNT < TIMx_CCRx, otherwise it becomes low. If the compare value in TIMx_CCRx is greater than the auto-reload value (in TIMx_ARR) then OCxREF is held at ‘1’. If the compare value is 0 then OCxRef is held at ‘0’. Figure 61 shows some edge-aligned PWM waveforms in an example where TIMx_ARR=8.

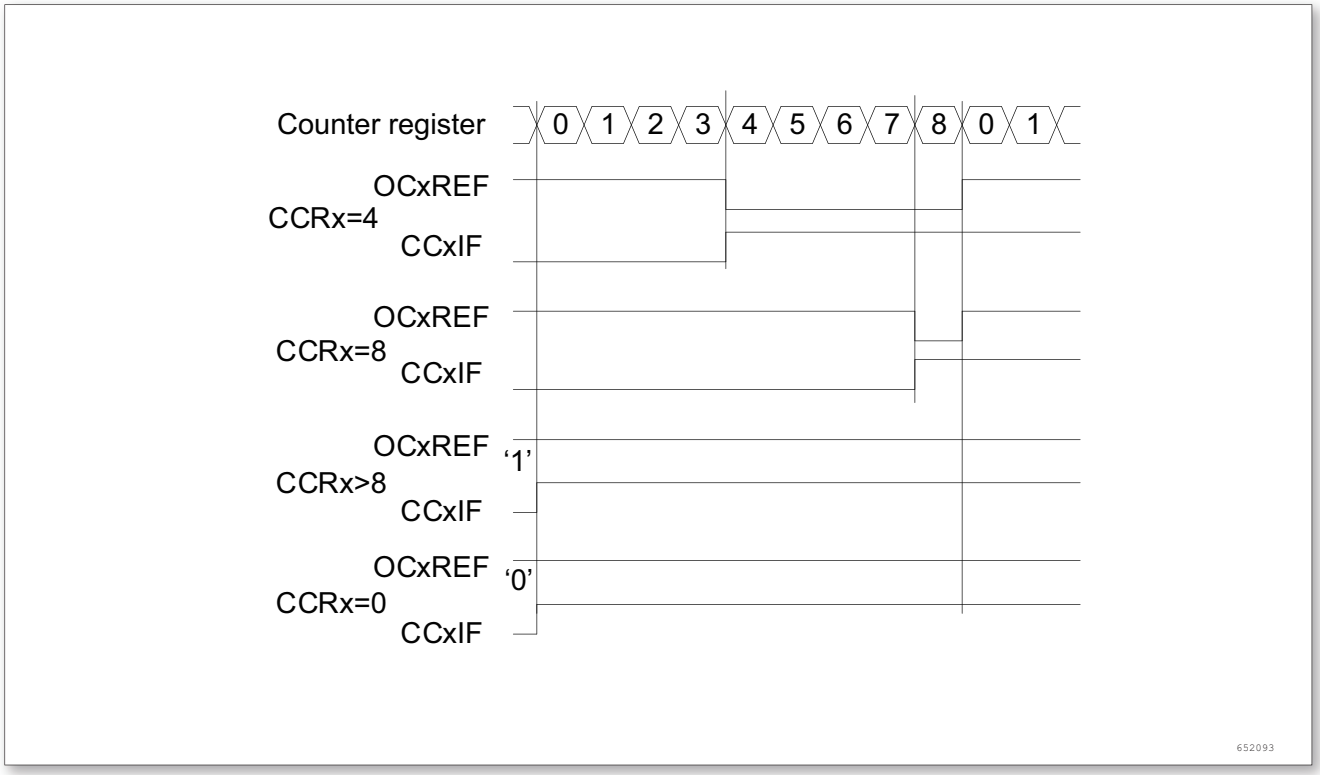

Figure 61. Edge-aligned PWM Waveforms (ARR = 8)

Downcounting configuration

Downcounting is active when DIR bit in TIMx_CR1 register is high. Refer to section 11.3.2.

In PWM mode 1, the reference signal OCxRef is low as long as TIMx_CNT > TIMx_CCRx, otherwise it becomes high. If the compare value in TIMx_CCRx is greater than the auto-reload value in TIMx_ARR, then OCxREF is held at ‘1’. 0% PWM is not possible in this mode.

PWM center-aligned mode

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are different from ‘00’ (all the remaining configurations having the same effect on the OCxRef/OCx signals). The compare flag is set when the counter counts up, when it counts down or when it counts up and down depending on the CMS bits configuration. The direction bit (DIR) in the TIMx_CR1 register is updated by hardware and must not be changed by software. Refer to section 11.3.2 Center-aligned Mode.

Figure 62 shows some center-aligned PWM waveforms in an example where:

- TIMx_ARR = 8
- PWM mode 1
- The flag is set when the counter counts down corresponding to the center-aligned mode 1 selected for CMS=01 in TIMx_CR1 register.

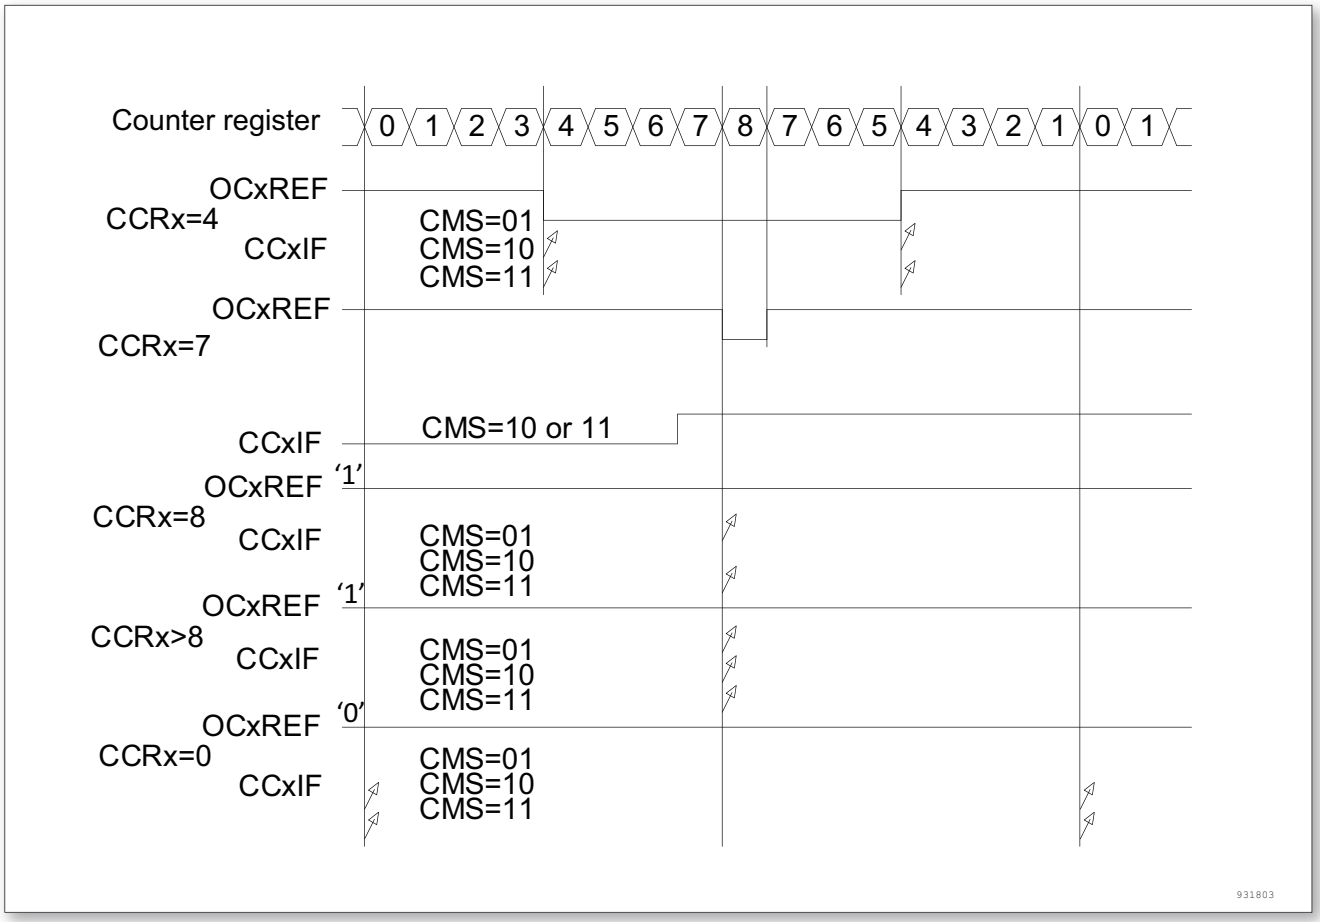

Figure 62. Center-aligned PWM Waveforms (ARR = 8)

Hints in center-aligned mode:

- When starting in center-aligned mode, the current up-down configuration is used. It means that the counter counts up or down depending on the value written in the DIR bit in the TIMx_CR1 register. Moreover, the DIR and CMS bits must not be changed at the same time by the software.
- Writing to the counter while running in center-aligned mode is not recommended as it can lead to unexpected results. In particular:
  - The direction is not updated if the user writes a value in the counter greater than the auto-reload value (TIMx_CNT>TIMx_ARR).
  - For example, if the counter was counting up, it will continue to count up.
  - The direction is updated if the user writes 0 or write the TIMx_ARR value in the counter but no Update Event UEV is generated
- The safest way to use center-aligned mode is to generate an update by software (setting the UG bit in the TIMx_EGR register) just before starting the counter and not to write

the counter while it is running.

11.3.11 Complementary outputs and dead-time insertion

The advanced-control timers (TIM1) can output two complementary signals and manage the switching-off and the switching-on instants of the outputs. This time is generally known as dead-time and it has to be adjusted depending on the devices connected to the outputs and their characteristics (intrinsic delays of level-shifters, delays due to power switches).

User can select the polarity of the outputs (main output OCx or complementary OCxN) independently for each output. This is done by writing to the CCxP and CCxNP bits in the TIMx_CCER register.

The complementary signals OCx and OCxN are activated by a combination of several control bits: the CCxE and CCxNE bits in the TIMx_CCER register and the MOE, OISx, OISxN, OSSI and OSSR bits in the TIMx_BDTR and TIMx_CR2 registers. Refer to Table 40 Output Control Bits for Complementary OCx and OCxN Channels with Break Feature for more details. In particular, the dead-time is activated when switching to the IDLE state (MOE falling down to 0).

Dead-time insertion is enabled by setting both CCxE and CCxNE bits, and the MOE bit if the break circuit is present. DTG[7:0] bits of the TIMx_BDTR register are used to control the dead-time generation for all channels. From a reference waveform OCxREF, it generates 2 outputs OCx and OCxN. If OCx and OCxN are active high:

- The OCxN output signal is the opposite of the reference signal except for the rising edge, which is delayed relative to the reference falling edge.
- The OCx output signal is the same as the reference signal except for the rising edge, which is delayed relative to the reference rising edge. If the delay is greater than the width of the active output (OCx or OCxN) then the corresponding pulse is not generated.

The following figures show the relationships between the output signals of the dead-time generator and the reference signal OCxREF(we suppose CCxP = 0, CCxNP = 0, MOE = 1, CCxE = 1 and CCxNE = 1 in these examples).

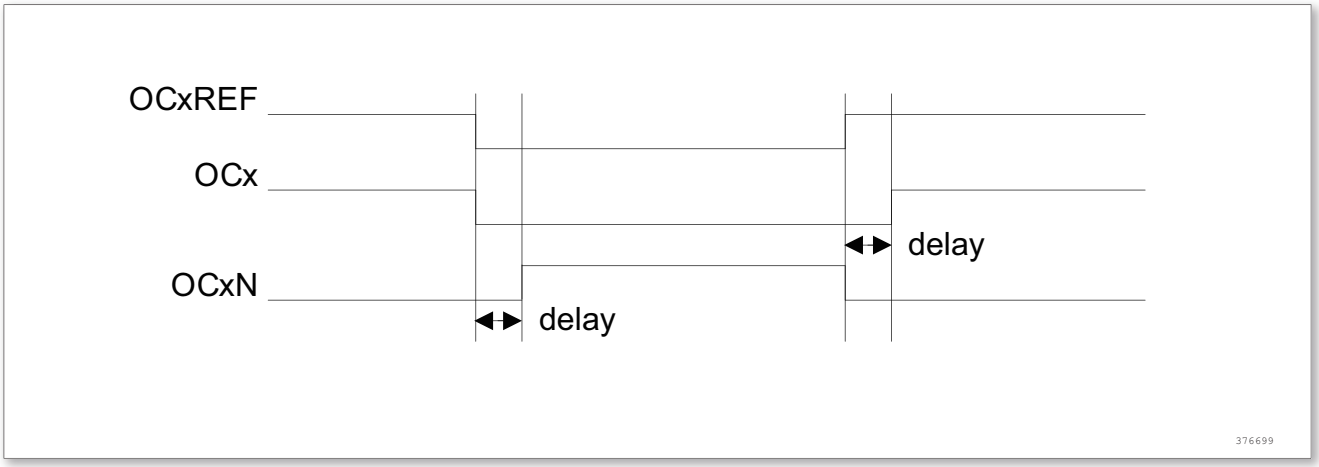

Figure 63. Complementary Output with Dead-time Insertion

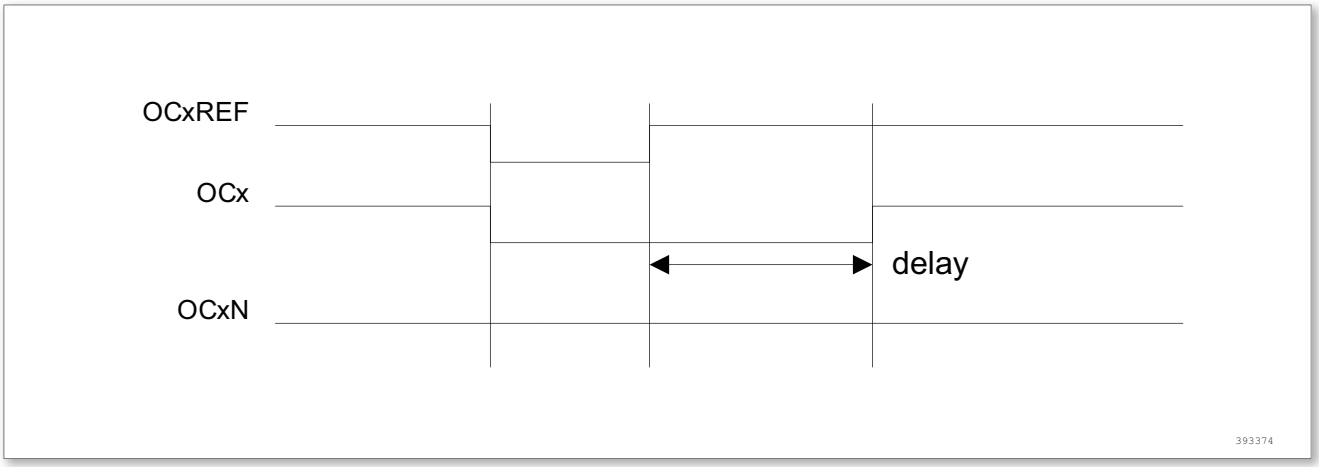

Figure 64. Dead-time Waveforms with Delay Greater Than the Negative Pulse

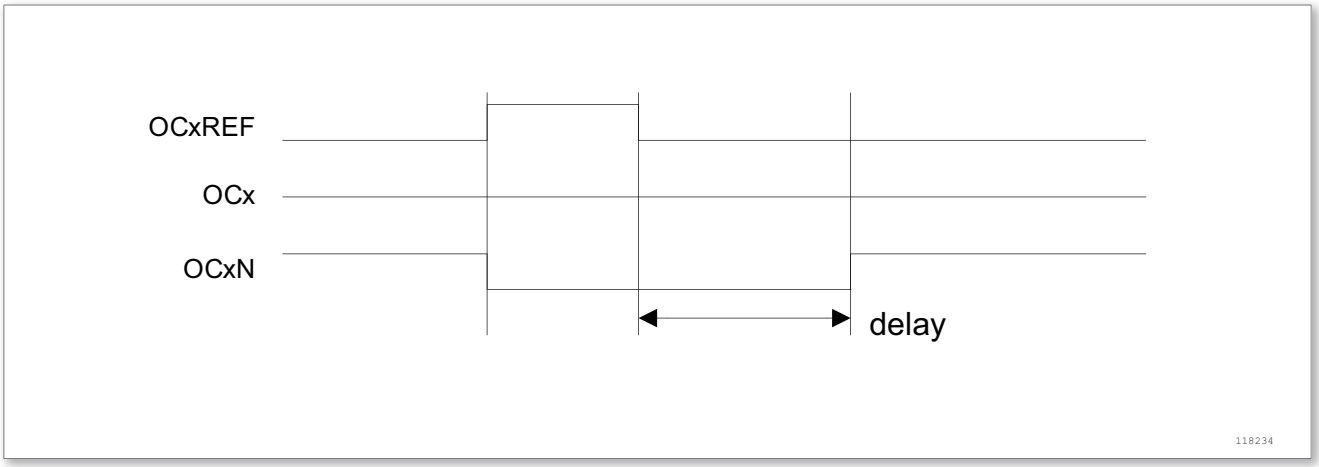

Figure 65. Dead-time Waveforms with Delay Greater than the Positive Pulse

The dead-time delay is the same for each of the channels and is programmable with the DTG bits in the TIMx_BDTR register. Refer to section 11.4.18 for delay calculation.

Re-directing OCxREF to OCx or OCxN

In output mode (forced, output compare or PWM), OCxREF can be re-directed to the OCx output or to OCxN output by configuring the CCxE and CCxNE bits in the TIMx_CCER register.

This allows the user to send a specific waveform (such as PWM or static active level) on one output while the complementary remains at its inactive level. Other possibilities are to have both outputs at inactive level or both outputs active and complementary with dead-time.

Note: When only OCxN is enabled (CCxE = 0, CCxNE = 1), it is not complemented and becomes active as soon as OCxREF is high. For example, if CCxNP = 0 then OCxN = OCxRef. On the other hand, when both OCx and OCxN are enabled (CCxE = CCxNE = 1) OCx becomes active when OCxREF is high whereas OCxN is complemented and becomes active when OCxREF is low.

11.3.12 Using the break function

When using the break function, the output enable signals and inactive levels are modified according to additional control bits (MOE, OSSI and OSSR bits in the TIMx_BDTR register,

OISx and OISxN bits in the TIMx_CR2 register). In any case, the OCx and OCxN outputs cannot be set both to active level at a given time. Refer to Table 40 Output Control Bits for Complementary OCx and OCxN Channels with Break Feature for more details.

The break source can be either the break input pin or a clock failure event, generated by the Clock Security System (CSS), from the Reset Clock Controller.

When exiting from reset, the break circuit is disabled and the MOE bit is low. User can enable the break function by setting the BKE bit in the TIMx_BDTR register. The break input polarity can be selected by configuring the BKP bit in the same register. BKE and BKP can be modified at the same time.

Because MOE falling edge can be asynchronous, a resynchronization circuit has been inserted between the actual signal (acting on the outputs) and the synchronous control bit (accessed in the TIMx_BDTR register). It results in some delays between the asynchronous and the synchronous signals. In particular, if MOE is written to 1 whereas it was low, a delay (dummy instruction) must be inserted before reading it correctly. This is because the user writes an asynchronous signal, but reads a synchronous signal.

When a break occurs (selected level on the break input):

- The MOE bit is cleared asynchronously, putting the outputs in inactive state, idle state or in reset state (selected by the OSSI bit). This feature functions even if the MCU oscillator is off.
- Each output channel is driven with the level programmed in the OISx bit in the TIMx_CR2 register as soon as MOE=0. If OSSI=0 then the timer releases the enable output otherwise the enable output remains high.
- In case of complementary output:
  - The outputs are first put in reset state i.e. inactive state (depending on the polarity). This is done asynchronously so that it works even if no clock is provided to the timer.
  - If the timer clock is still present, the dead-time generator is reactivated in order to drive the outputs with the level programmed in the OISx and OISxN bits after a dead-time. Even in this case, OCx and OCxN cannot be driven to their active level together. Note that because of the resynchronization on MOE, the dead-time duration is a bit longer than usual (around 2 CK_TIM clock cycles).
  - If OSSI = 0 then the timer releases the enable outputs otherwise the enable outputs remain or become high as soon as one of the CCxE or CCxNE bits is high.
- The break status flag (BIF bit in the TIMx_SR register) is set. An interrupt can be generated if the BIE bit in the TIMx_DIER register is set. A DMA request can be sent if the BDE bit in the TIMx_DIER register is set.
- If the AOE bit in the TIMx_BDTR register is set, the MOE bit is automatically set again at the next update event UEV. This can be used to perform a regulation, for instance. Otherwise, MOE remains low until it is written to ‘1’ again. In this case, it can be used for security and the break input can be connected to an alarm from power drivers, thermal sensors or any security components.

Note: The break inputs is acting on level. Thus, the MOE cannot be set while the break input is active (neither automatically nor by software). In the meantime, the status flag BIF cannot be cleared.

The break can be generated by the BRK input which has a programmable polarity and an enable bit BKE in the TIMx_BDTR Register.

In addition to the break input and the output management, a write protection has been implemented inside the break circuit to safeguard the application. It allows freezing the configuration of several parameters (dead-time duration, OCx/OCxN polarities and state when disabled, OCxM configurations, break enable and polarity). The user can choose from three levels of protection selected by the LOCK bits in the TIMx_BDTR register. Refer to Section 11.4.8. The LOCK bits can be written only once after an MCU reset.

The following figure shows an example of behavior of the outputs in response to a break:

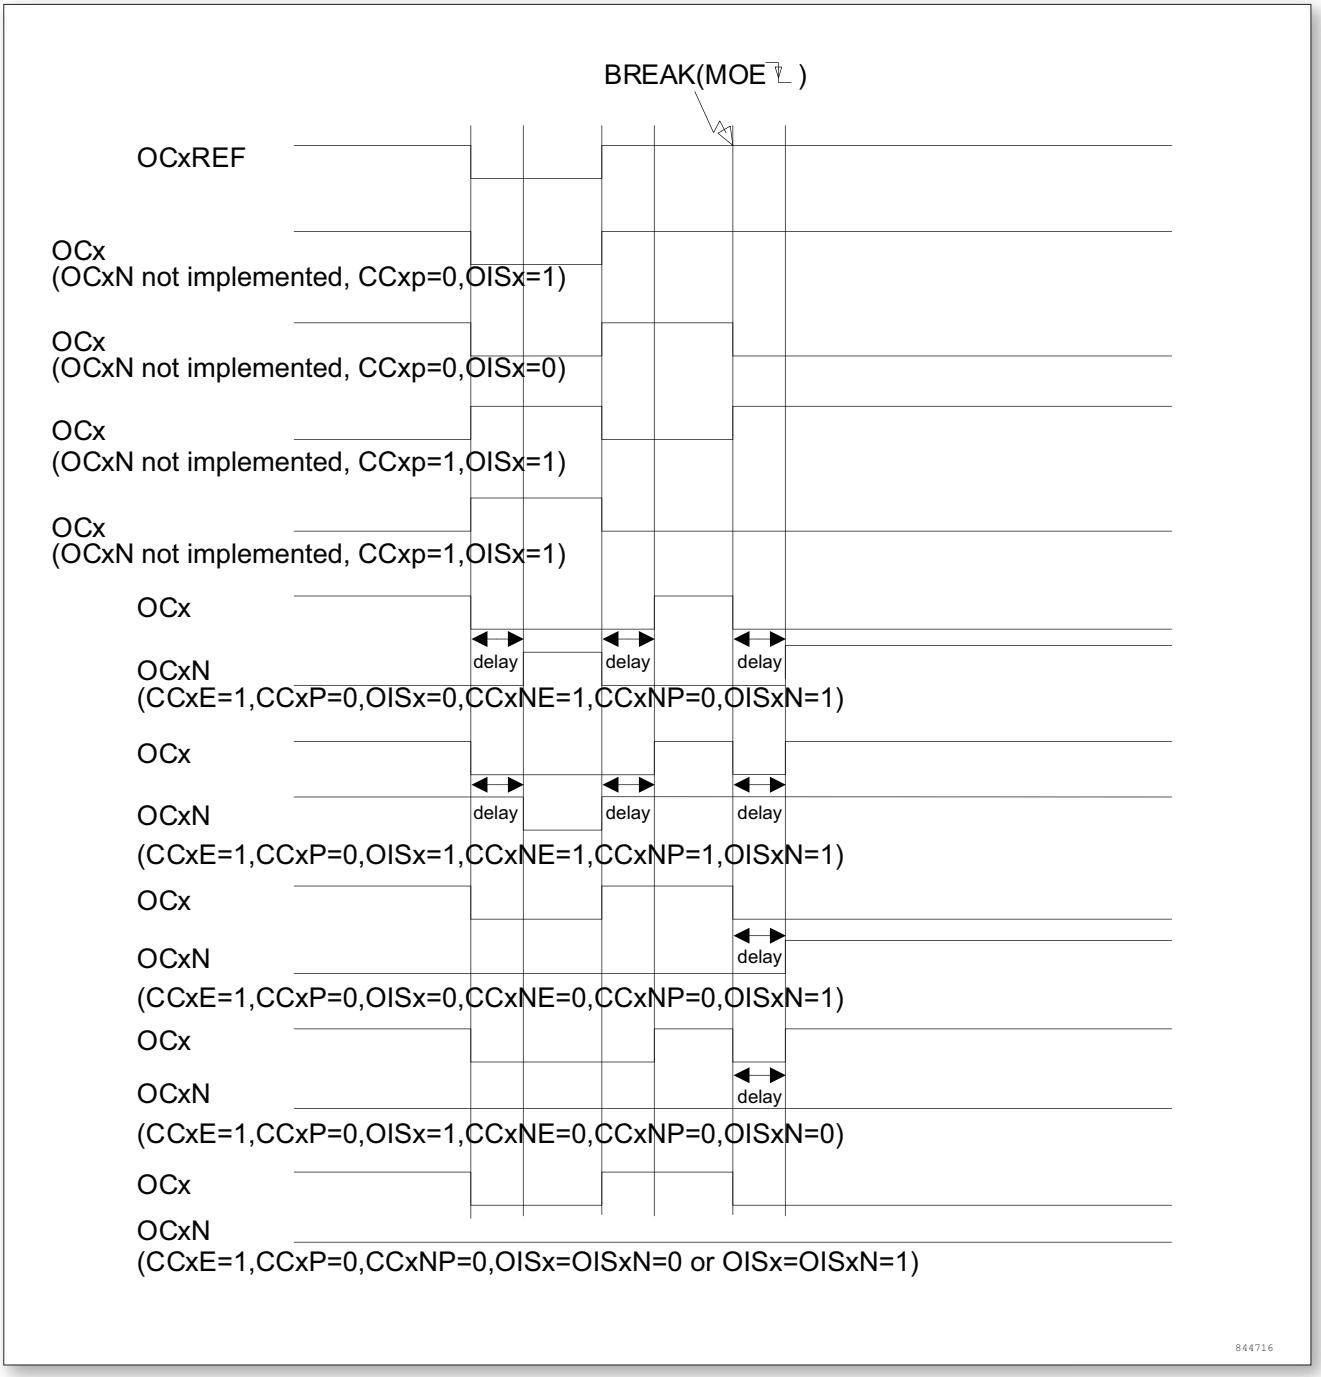

Figure 66. Output Behavior in Response to A Break

11.3.13 Clearing the OCxREF signal on an external event

The OCxREF signal for a given channel can be driven Low by applying a High level to the ETRF input (OCxCE enable bit of the corresponding TIMx_CCMRx register set to ‘1’). The OCxREF signal remains Low until the next update event, UEV, occurs.

This function can only be used in output compare and PWM modes, and does not work in forced mode.

For example, the ETR signal can be connected to the output of a comparator to be used for current handling. In this case, the ETR must be configured as follow:

- The External Trigger Prescaler should be kept off: bits ETPS[1:0] of the TIMx_SMCR register set to ‘00’.
- The external clock mode 2 must be disabled: bit ECE of the TIMx_SMCR register set to ‘0’.
- The External Trigger Polarity (ETP) and the External Trigger Filter (ETF) can be configured according to the user needs.

The following Figure shows the behavior of the OCxREF signal when the ETRF Input becomes High, for both values of the enable bit OCxCE. In this example, the timer TIMx is programmed in PWM mode.

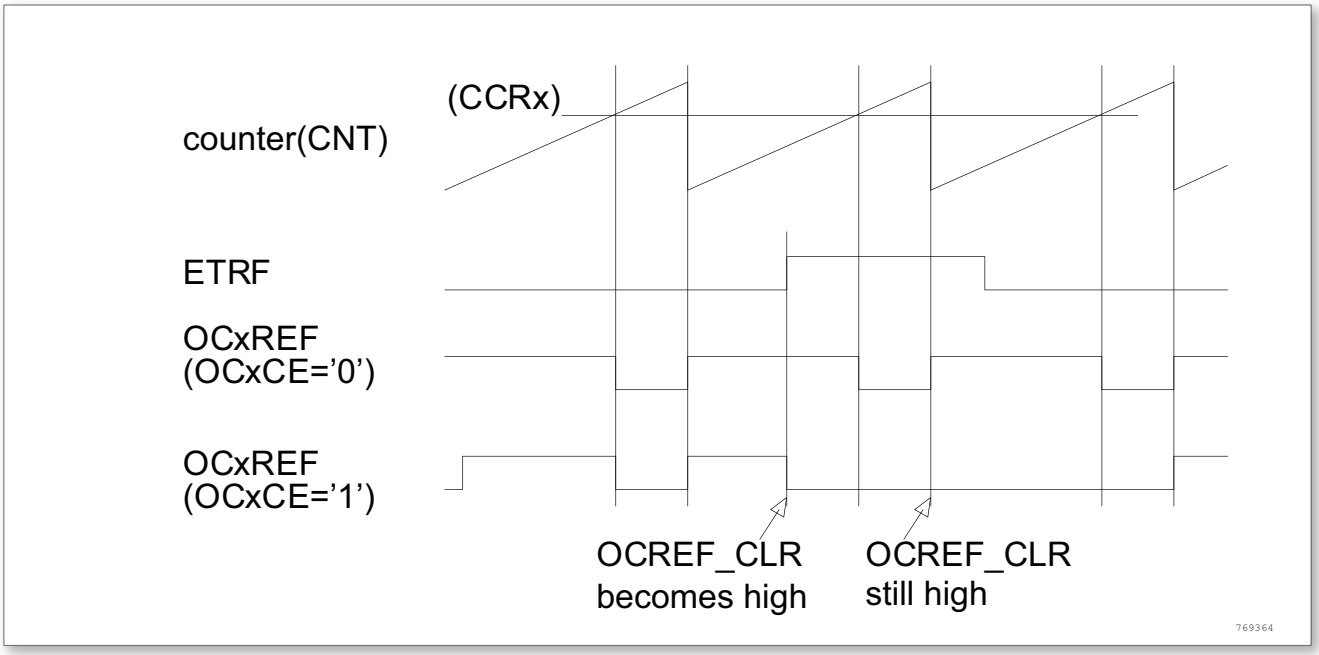

Figure 67. Clearing TIMx OCxREF

11.3.14 Six-step PWM generation

When complementary outputs are used on a channel, preload bits are available on the OCxM, CCxE and CCxNE bits. The preload bits are transferred to the shadow bits at the COM commutation event. The user can thus program in advance the configuration for the next step and change the configuration of all the channels at the same time. COM can be generated by software by setting the COM bit in the TIMx_EGR register or by hardware (on TRGI rising edge).

A flag is set when the COM event occurs (COMIF bit in the TIMx_SR register), which can generate an interrupt (if the COMIE bit is set in the TIMx_DIER register) or a DMA request (if the COMDE bit is set in the TIMx_DIER register).

The following figure describes the behavior of the OCx and OCxN outputs when a COM event occurs, in 3 different examples of programmed configurations.

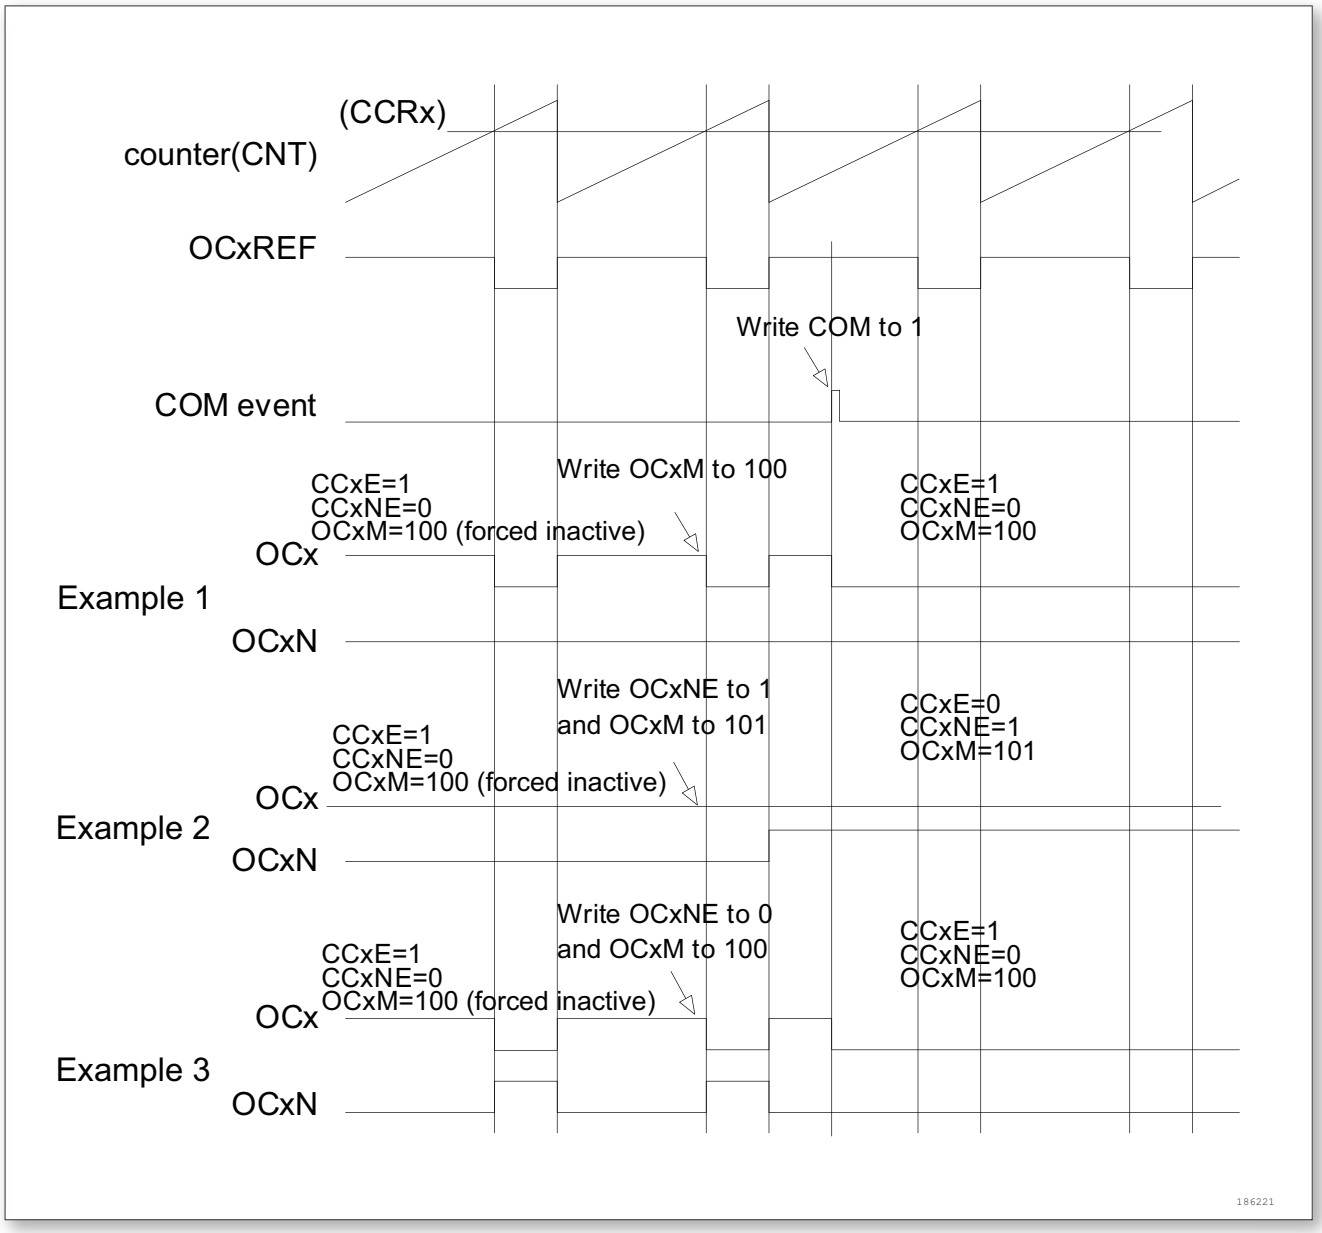

Figure 68. Six-step PWM, COM Example (OSSR = 1)

11.3.15 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. Select One-pulse mode by setting the OPM bit in the TIMx_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- In upcounting: CNT < CCRx ≤ ARR (in particular, 0 < CCRx)
- In downcounting: CNT > CCRx

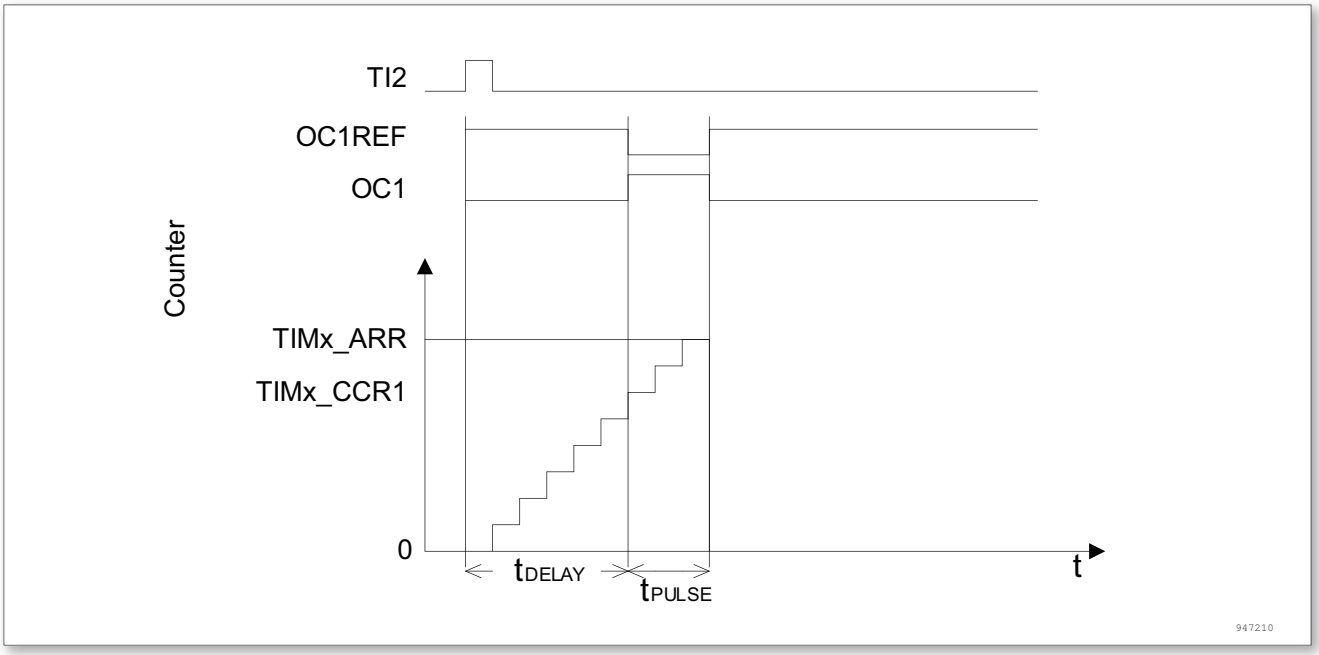

Figure 69. Example of One Pulse Mode

For example the user may want to generate a positive pulse on OC1 with a length of t_{PULSE} and after a delay of t_{DELAY} as soon as a positive edge is detected on the TI2 input pin.

Let’ s use TI2FP2 as trigger 1:

- Map TI2FP2 to TI2 by writing CC2S = ’01’ in the TIMx_CCMR1 register.
- TI2FP2 must detect a rising edge, write CC2P = ’0’ in the TIMx_CCER register.
- Configure TI2FP2 as trigger for the slave mode controller (TRGI) by writing TS = ’110’ in the TIMx_SMCR register.
- TI2FP2 is used to start the counter by writing SMS to ’110’ in the TIMx_SMCR register (trigger mode).

The OPM waveform is defined by the value written in the compare registers (taking into account the clock frequency and the counter prescaler)

- The t_{DELAY} is defined by the value written in the TIMx_CCR1 register.
- The t_{PULSE} is defined by the difference between the auto-reload value and the compare value (TIMx_ARR - TIMx_CCR1).
- Let us say the user wants to build a waveform with a transition from ’0’ to ’1’ when a compare match occurs and a transition from ‘1’ to ‘0’ when the counter reaches the auto-reload value. To do this, enable PWM mode 2 by writing OC1M=111 in the TIMx_CCMR1 register. The user can optionally enable the preload registers by writing OC1PE=’1’ in the TIMx_CCMR1 register and ARPE in the TIMx_CR1 register. In this case the compare value must be written in the TIMx_CCR1 register, the auto-reload value in the TIMx_ARR register, generate an update by setting the UG bit and wait for external trigger event on TI2. CC1P is written to ‘0’ in this example.

In our example, the DIR and CMS bits in the TIMx_CR1 register should be low.

The user only wants one pulse (Single mode), so ’1’ must be written in the OPM bit in the TIMx_CR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0).

Particular case: OCx fast enable

In One-pulse mode, the edge detection on TIx input sets the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay t_{DELAY} min we can get.

If the user wants to output a waveform with the minimum delay, the OCxFE bit in the TIMx_CCMRx register must be set. Then OCxRef (and OCx) are forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

11.3.16 Encoder interface mode

To select Encoder Interface mode: write SMS = ’001’ in the TIMx_SMCR register if the counter is counting on TI2 edges only, SMS = ’010’ if it is counting on TI1 edges only and SMS = ’011’ if it is counting on both TI1 and TI2 edges.

Select the TI1 and TI2 polarity by programming the CC1P and CC2P bits in the TIMx_CCER register. When needed, the user can program the input filter as well. The two inputs TI1 and TI2 are used to interface to an incremental encoder. Refer to Table 37. The counter is clocked by each valid transition on TI1FP1 or TI2FP2 (TI1 and TI2 after input filter and polarity selection, TI1FP1=TI1 if not filtered and not inverted, TI2FP2=TI2 if not filtered and not inverted) assuming that it is enabled (CEN bit in TIMx_CR1 register written to ‘1’). The sequence of transitions of the two inputs is evaluated and generates count pulses as well as the direction signal. Depending on the sequence the counter counts up or down, the DIR bit in the TIMx_CR1 register is modified by hardware accordingly. The DIR bit is calculated at each transition on any input (TI1 or TI2), whatever the counter is counting on TI1 only, TI2 only or both TI1 and TI2.

Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the auto-reload value in the TIMx_ARR register (0 to ARR or ARR down to 0 depending on the direction). So user must configure TIMx_ARR before starting. In the same way, the capture, compare, prescaler, repetition counter, trigger output features continue to work as normal. Encoder mode and External clock mode 2 are not compatible and must not be selected together.

In this mode, the counter is modified automatically following the speed and the direction of the incremental encoder and its content, therefore, always represents the encoder’s position. The count direction corresponds to the rotation direction of the connected sensor. The following table summarizes the possible combinations, assuming TI1 and TI2 do not switch at the same time.

Table 37. Counting Direction Versus Encoder Signals

Active edge	Level on opposite signal (TI1FP1 for TI2, TI2FP2 for TI1)	TI1FP1 signal		TI1FP2 signal	
		Rising	Falling	Rising	Falling
Counting on TI1 only	High	Down	Up	No Count	No Count
	Low	Up	Down	No Count	No Count
Counting on TI2 only	High	No Count	No Count	Up	Down
	Low	No Count	No Count	Down	Up
Counting on TI1 and TI2	High	Down	Up	Up	Down
	Low	Up	Down	Down	Up

An external incremental encoder can be connected directly to the MCU without external interface logic. However, comparators are normally used to convert the encoder's differential outputs to digital signals. This greatly increases noise immunity. The third encoder output which indicates the mechanical zero position, may be connected to an external interrupt input and trigger a counter reset.

The following figure gives an example of counter operation, showing count signal generation and direction control. It also shows how input jitter is restrained where both edges are selected. This might occur if the sensor is positioned near to one of the switching points.

For this example we assume that the configuration is the following:

- CC1S='01' (TIMx_CCMR1 register, TI1FP1 mapped on TI1).
- CC2S='01' (TIMx_CCMR2 register, TI1FP2 mapped on TI2).
- CC1P='0', (TIMx_CCER register, IC1FP1 non-inverted, IC1FP1=TI1).
- C2P= '0' (TIMx_CCER register, IC2FP2 non-inverted, IC2FP2=TI2).
- SMS= '011' (TIMx_SMCR register, all inputs are active on both rising and falling edges).
- CEN= '1' (TIMx_CR1 register, Counter enabled).

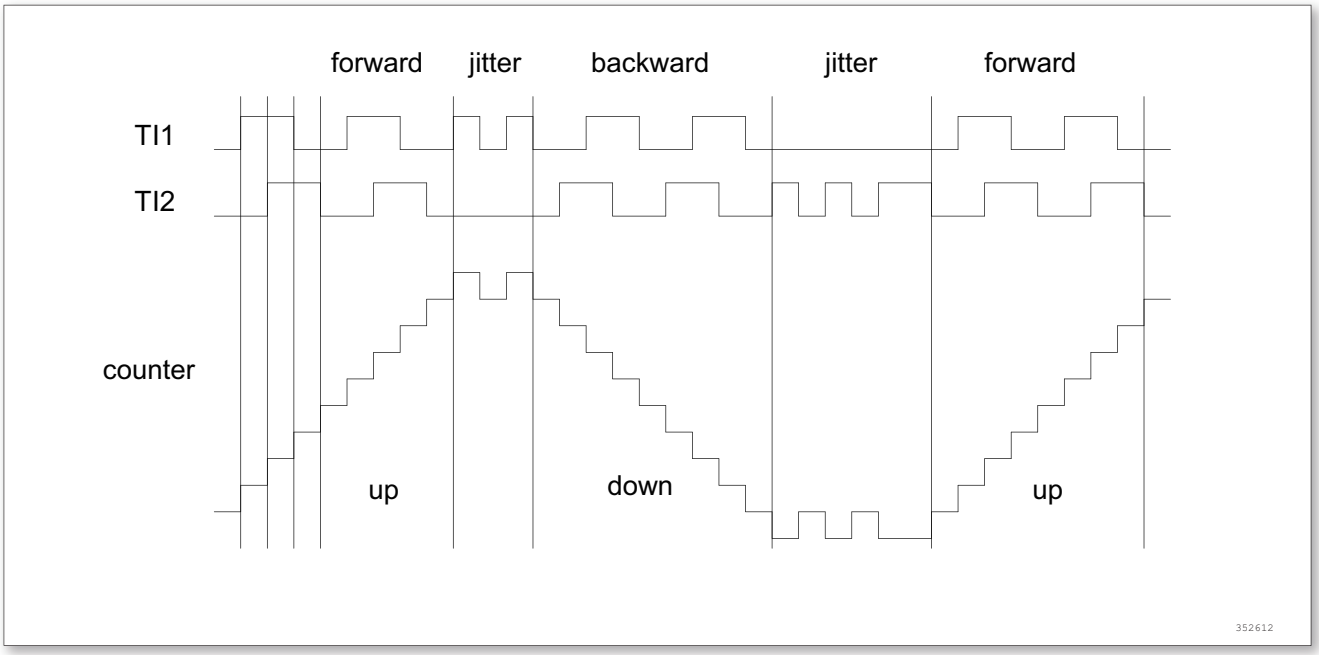

Figure 70. Example of Counter Operation in Encoder Mode

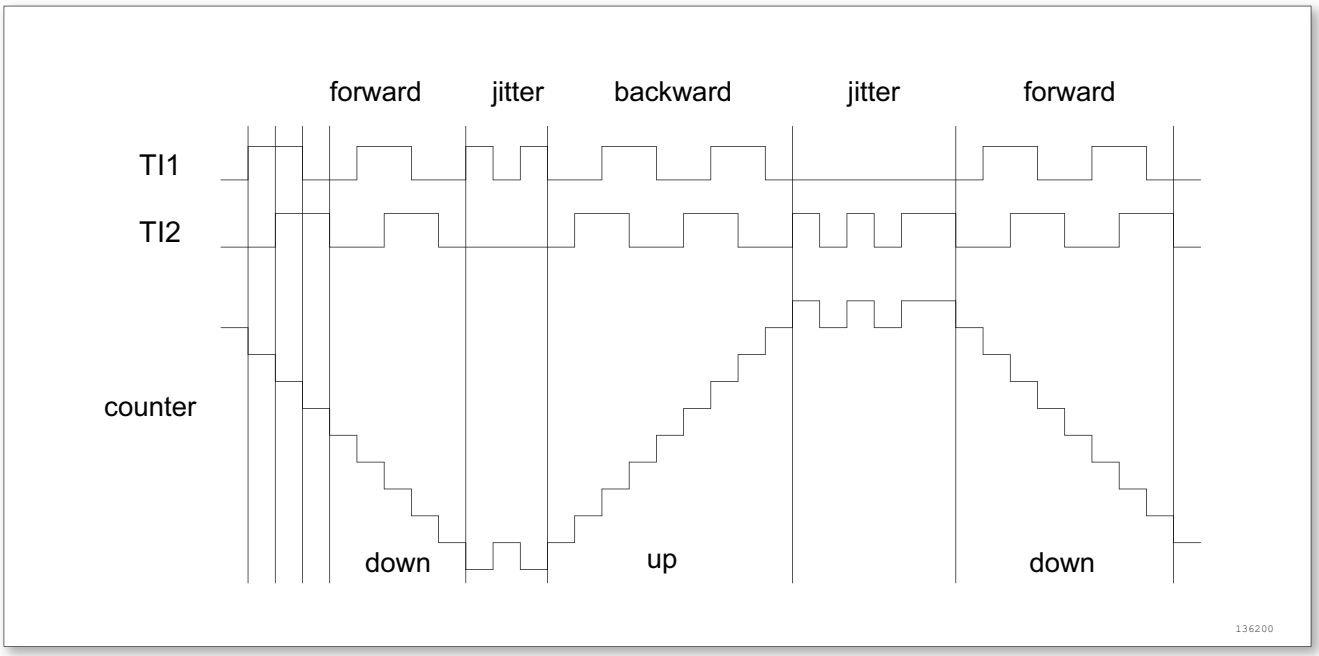

Figure 71. Example of Encoder Interface Mode with Inverted IC1FP1

The timer, when configured in Encoder Interface mode provides information on the sensor’ s current position.The user can obtain dynamic information (speed, acceleration, deceleration) by measuring the period between two encoder events using a second timer configured in capture mode. The output of the encoder which indicates the mechanical zero can be used for this purpose. Depending on the time between two events, the counter can also be read at regular times.

This can be done by latching the counter value into a third input capture register if available (then the capture signal must be periodic and can be generated by another timer). When available, it is also possible to read its value through a DMA request generated by a real-time clock.

11.3.17 Timer input XOR function

The TI1S bit in the TIMx_CR2 register, allows the input filter of channel 1 to be connected to the output of a XOR gate, combining the three input pins TIMx_CH1, TIMx_CH2 and TIMx_CH3.

The XOR output can be used with all the timer input functions such as trigger or input capture. An example of this feature used to interface Hall sensors is given in section 11.3.18.

11.3.18 Interfacing with Hall sensors

This is done using the advanced-control timers (TIM1) to generate PWM signals to drive the motor and another timer TIMx (TIM2 or TIM3) referred to as ”interfacing timer” in Figure 72. The ”interfacing timer” captures the 3 timer input pins (CC1, CC2, CC3) connected through an XOR to the TI1 input channel (selected by setting the TI1S bit in the TIMx_CR2 register).

The slave mode controller is configured in reset mode; the slave input is TI1F_ED. Thus,

each time one of the 3 inputs toggles, the counter restarts counting from 0. This creates a time base triggered by any change on the Hall inputs.

On the “interfacing timer”, capture/compare channel 1 is configured in capture mode, capture signal is TRC (see Figure 55). The captured value, which corresponds to the time elapsed between 2 changes on the inputs, gives information about motor speed.

The “interfacing timer” can be used in output mode to generate a pulse which changes the configuration of the channels of the advanced-control timer TIM1 (by triggering a COM event). The TIM1 timer is used to generate PWM signals to drive the motor. To do this, the interfacing timer channel must be programmed so that a positive pulse is generated after a programmed delay (in output compare or PWM mode). This pulse is sent to the advanced-control timer (TIM1) through the TRGO output.

Example: the user wants to change the PWM configuration of the advanced-control timer TIMx after a programmed delay each time a change occurs on the Hall inputs connected to one of the TIMx timers.

- Configure 3 timer inputs ORed to the TI1 input channel by writing the TI1S bit in the TIMx_CR2 register to ’1’.
- Program the time base: write the TIMx_ARR to the max value (the counter must be cleared by the TI1 change. Set the prescaler to get a maximum counter period longer than the time between 2 changes on the sensors.
- Program channel 1 in capture mode (TRC selected): write the CC1S bits in the TIMx_CCMR1 register to ‘01’. The user can also program the digital filter if needed.
- Program channel 2 in PWM 2 mode with the desired delay: write the OC2M bits to ‘111’ and the CC2S bits to ‘00’ in the TIMx_CCMR1 register.
- Select OC2REF as trigger output on TRGO: write the MMS bits in the TIMx_CR2 register to ‘101’.

In the advanced-control timer TIM1, the right ITR input must be selected as trigger input, the timer is programmed to generate PWM signals, the capture/compare control signals are preloaded (CCPC=1 in the TIMx_CR2 register) and the COM event is controlled by the trigger input (CCUS=1 in the TIMx_CR2 register). The PWM control bits (CCxE, OCxM) are written after a COM event for the next step (this can be done in an interrupt subroutine generated by the rising edge of OC2REF).

The following figure describes this example.

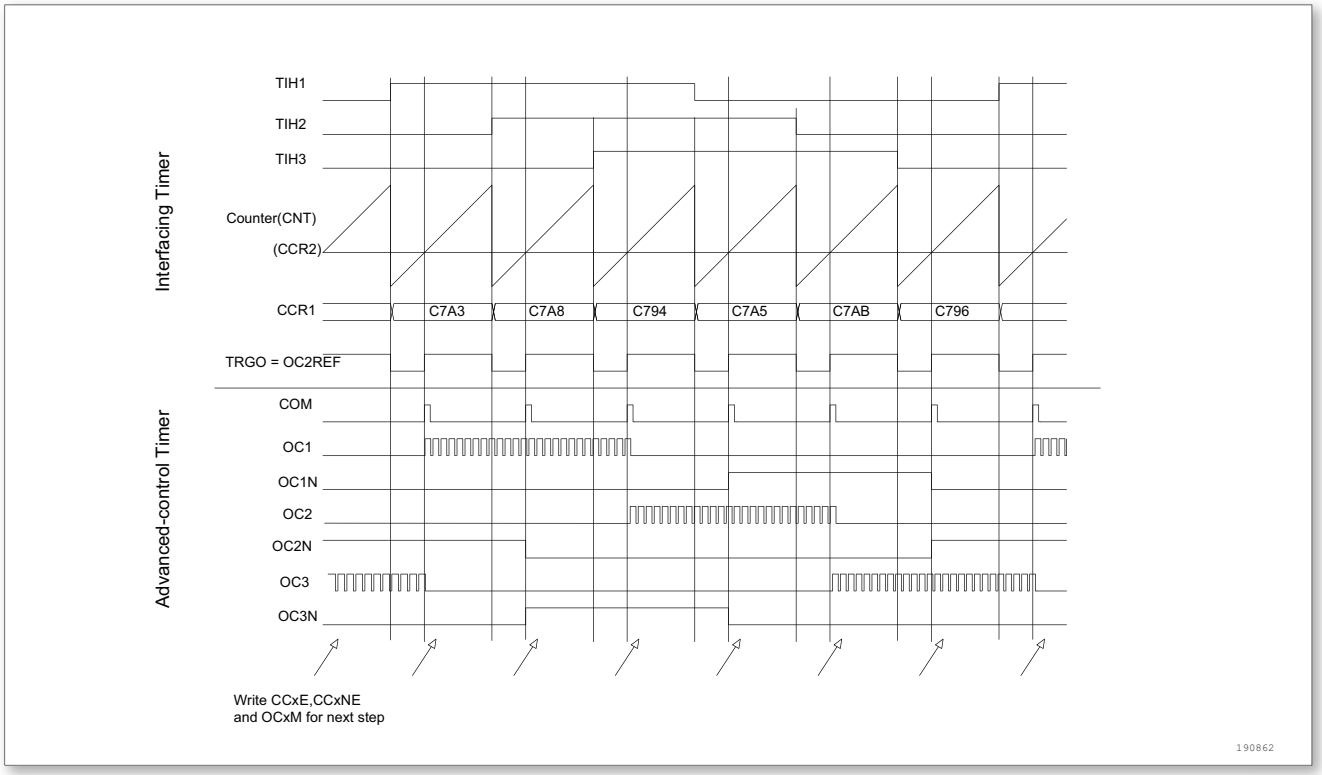

Figure 72. Example of Hall Sensor Interface

11.3.19 TIMx and external trigger synchronization

The TIMx timer can be synchronized with an external trigger in several modes: Reset mode, Gated mode and Trigger mode.

Slave mode: Reset mode

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx_CR1 register is low, an update event UEV is generated. Then, all the preloaded registers (TIMx_ARR, TIMx_CCRx) are updated.

In the following example, the upcounter is cleared in response to a rising edge on TI1 input:

- Configure the channel 1 to detect rising edges on TI1. Configure the input filter duration (in this example, we don’t need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so there’s no need to configure it. The CC1S bits select the input capture source only, CC1S = 01 in the TIMx_CCMR1 register. Write CC1P=0 in TIMx_CCER register to validate the polarity (and detect rising edges only).
- Configure the timer in reset mode by writing SMS=100 in TIMx_SMCR register. Select TI1 as the input source by writing TS=101 in TIMx_SMCR register.
- Start the counter by writing CEN=1 in the TIMx_CR1 register.

The counter starts counting on the internal clock, then behaves normally until TI1 rising edge. When TI1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIMx_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE (interrupt enable) and TDE (DMA

enable) bits in TIMx_DIER register).

The following figure shows this behavior when the auto-reload register TIMx_ARR=0x36. The delay between the rising edge on TI1 and the actual reset of the counter is due to the resynchronization circuit on TI1 input.

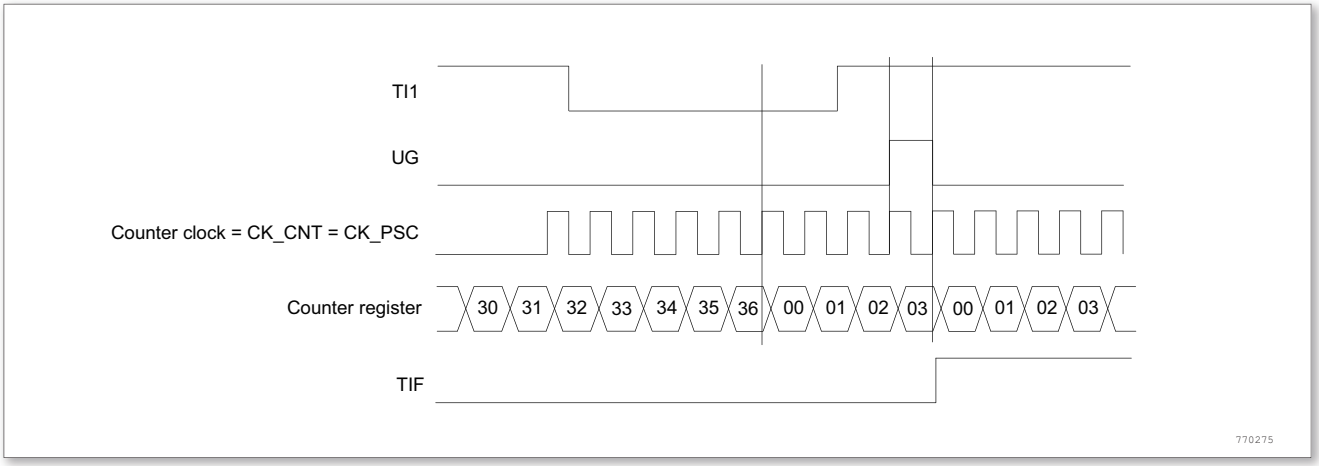

Figure 73. Control Circuit in Reset Mode

Slave mode: Gated mode

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when TI1 input is low:

- Configure the channel 1 to detect low levels on TI1. Configure the input filter duration (in this example, we don't need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so the user does not need to configure it. The CC1S bits select the input capture source only, CC1S=01 in TIMx_CCMR1 register. Write CC1P=1 in TIMx_CCER register to validate the polarity (and detect low level only)
- Configure the timer in gated mode by writing SMS=101 in TIMx_SMCR register. Select TI1 as the input source by writing TS=101 in TIMx_SMCR register.
- Enable the counter by writing CEN=1 in the TIMx_CR1 register (in gated mode, the counter doesn't start if CEN=0, whatever the trigger input level is)

The counter starts counting on the internal clock as long as TI1 is low and stops as soon as TI1 becomes high. The TIF flag in the TIMx_SR register is set both when the counter starts or stops.

The delay between the rising edge on TI1 and the actual stop of the counter is due to the resynchronization circuit on TI1 input.

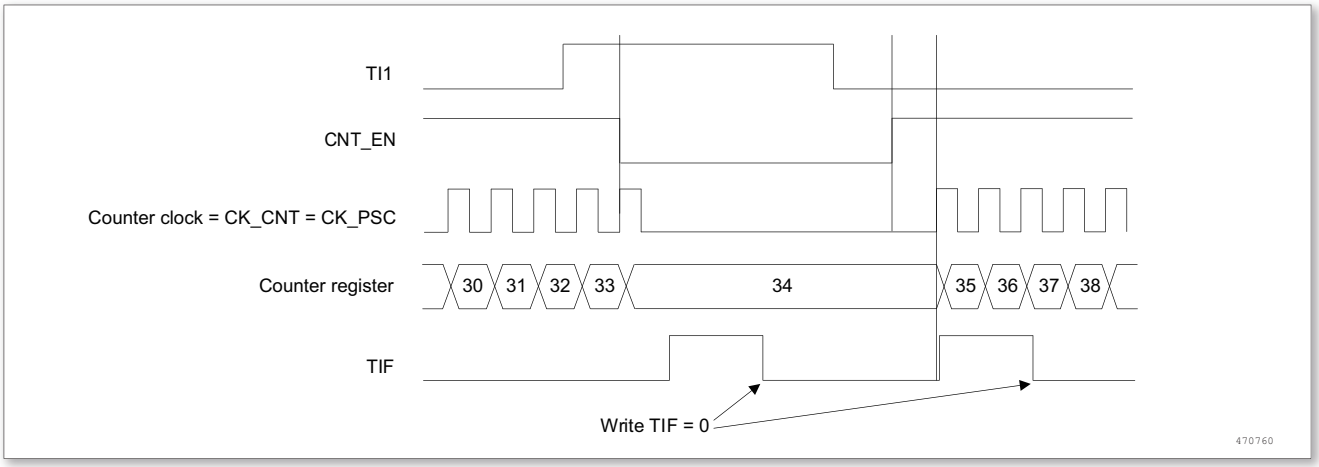

Figure 74. Control Circuit in Gated Mode

Slave mode: Trigger mode

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on TI2 input:

- Configure the channel 2 to detect rising edges on TI2. Configure the input filter duration (in this example, we don't need any filter, so we keep IC2F=0000). The capture prescaler is not used for triggering, so there's no need to configure it. The CC2S bits are only configured to select CC2P=1 in TIMx_CCER register, so as to validate the polarity (and detect low level only).
- Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select TI2 as the input source by writing TS=110 in TIMx_SMCR register.

When a rising edge occurs on TI2, the counter starts counting on the internal clock and the TIF flag is set. The delay between the rising edge on TI2 and the actual start of the counter is due to the resynchronization circuit on TI2 input.

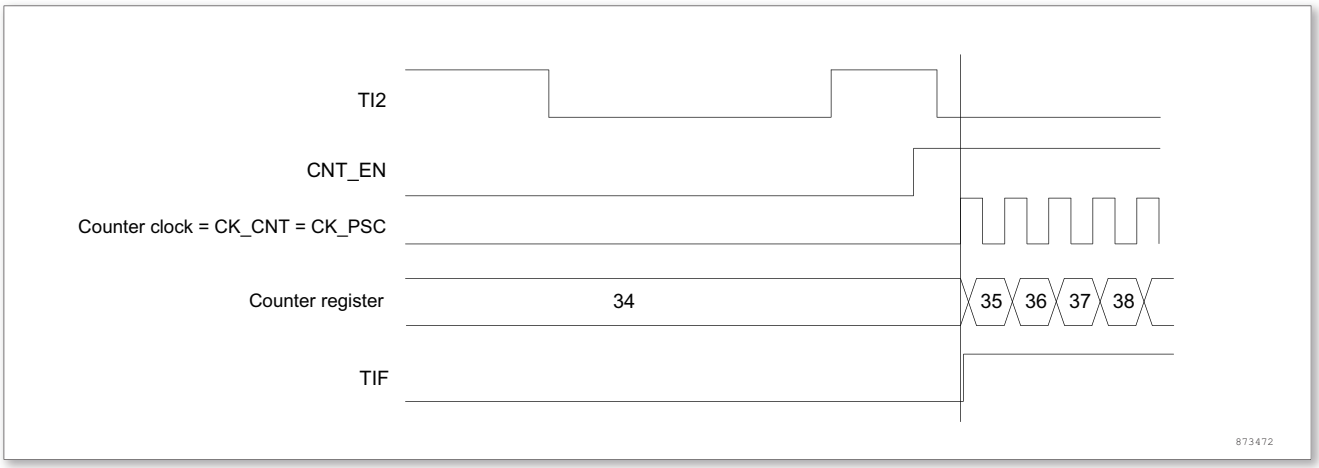

Figure 75. Control Circuit in Trigger Mode

Slave mode: external clock mode 2 + trigger mode

The external clock mode 2 can be used in addition to another slave mode (except external clock mode 1 and encoder mode). In this case, the ETR signal is used as external clock

input, and another input can be selected as trigger input (in reset mode, gated mode or trigger mode). It is recommended not to select ETR as TRGI through the TS bits of TIMx_SMCR register.

In the following example, the upcounter is incremented at each rising edge of the ETR signal as soon as a rising edge of TI1 occurs:

- Configure the external trigger input circuit by programming the TIMx_SMCR register as follows:
  - ETF = 0000: no filter
  - ETPS = 00: prescaler disabled
  - ETP = 0: detection of rising edges on ETR and ECE=1 to enable the external clock mode 2.
- Configure the channel 1 as follows, to detect rising edges on T1:
  - IC1F=0000: no filter.
  - The capture prescaler is not used for triggering and does not need to be configured.
  - CC1S=01 in TIMx_CCMR1 register to select only the input capture source.
  - CC1P=0 in TIMx_CCER register to validate the polarity (and detect rising edge only).
- Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select TI1 as the input source by writing TS=101 in TIMx_SMCR register

A rising edge on TI1 enables the counter and sets the TIF flag. The counter then counts on ETR rising edges.

The delay between the rising edge of the ETR signal and the actual reset of the counter is due to the resynchronization circuit on ETRP input.

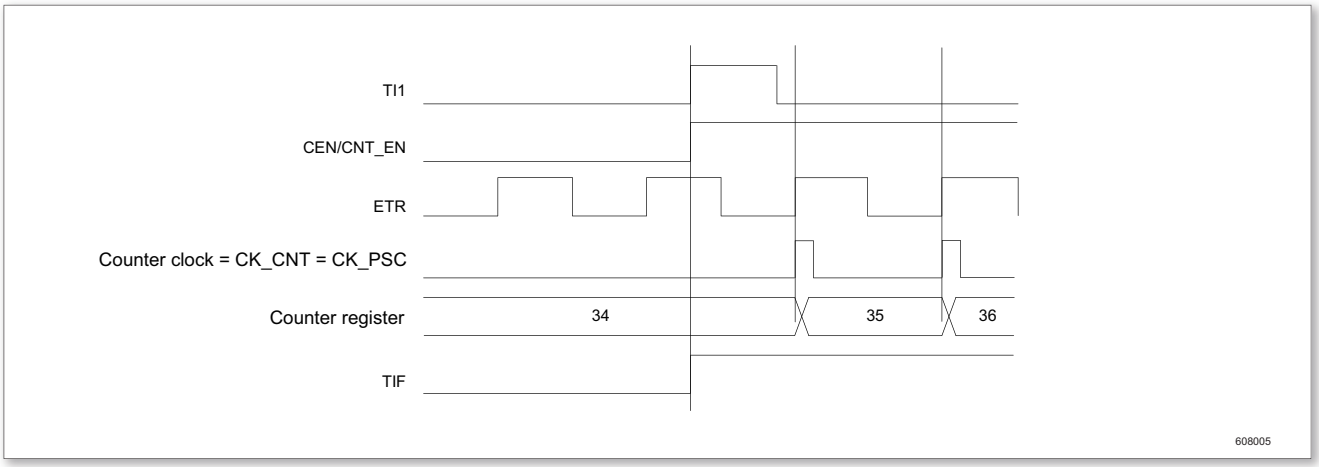

Figure 76. Control Circuit in External Clock Mode 2 + Trigger Mode

11.3.20 Timer synchronization

The TIM timers are linked together internally for timer synchronization or chaining. Refer to Section TIM2/3/4 for details.

11.3.21 Debug mode

When the microcontroller enters debug mode (CPU core halted), the TIMx counter either continues to work normally or stops, depending on DBG_TIMx_STOP configuration bit in DBG module. For more details, refer to the following debug sections.

6: 5	CMS	rw	0x00	Center-aligned mode selection 00: Edge-aligned mode. The counter counts up or down depending on the direction bit (DIR). 01: Center-aligned mode 1. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set only when the counter is counting down. 10: Center-aligned mode 2. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set only when the counter is counting up. 11: Center-aligned mode 3. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set both when the counter is counting up or down. Note: It is not allowed to switch from edge-aligned mode to center-aligned mode when the counter is enabled (CEN=1).
4	DIR	rw	0x00	Direction 0: Counter used as upcounter 1: Counter used as downcounter Note: This bit is read only when the timer is configured in Center-aligned mode or Encoder mode.
3	OPM	rw	0x00	One pulse mode 0: Counter is not stopped at update event 1: Counter stops counting at the next update event (clearing the bit CEN)

Bit	Field	Type	Reset	Description
2	URS	rw	0x00	Update request source This bit is set and cleared by software to select the UEV event sources. 0: Any of the following events generates an update interrupt or DMA request if enabled.These events can be: - Counter overflow/underflow - Setting the UG bit - Update generation through the slave mode controller 1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.
1	UDIS	rw	0x00	Update disable This bit is set and cleared by software to enable/disable UEV event generation. 0: UEV enabled. The Update (UEV) event is generated by one of the following events: - Counter overflow/underflow - Setting the UG bit - Update generation through the slave mode controller, buffered registers are then loaded with their preload values 1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.
0	CEN	rw	0x00	Counter enable 0: Counter disabled 1: Counter enabled Note: External clock, gated mode and encoder mode can work only if the CEN bit has been previously set by software. However, trigger mode can set the CEN bit automatically by hardware.

11.4.2 Control register 2(TIMx_CR2)

Offset address: 0x04

Bit	Field	Type	Reset	Description
15	Reserved			Reserved, always read as 0.
14	OIS4	rw	0x00	Output Idle state 4 (OC4 output).Refer to OIS1 bit.
13	OIS3N	rw	0x00	Output Idle state 3(OC3N output). Refer to OIS1N bit.
12	OIS3	rw	0x00	Output Idle state 4 (OC4 output).Refer to OIS1 bit.
11	OIS2N	rw	0x00	Output Idle state 3(OC3N output). Refer to OIS1N bit.
10	OIS2	rw	0x00	Output Idle state 4 (OC4 output).Refer to OIS1 bit.
9	OIS1N	rw	0x00	Output Idle state 1 (OC1N output) 0: OC1N=0 after a dead-time when MOE=0 1: OC1N=1 after a dead-time when MOE=0 Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BKR register).
8	OIS1	rw	0x00	Output Idle state 1 (OC1 output) 0: OC1=0 (after a dead-time if OC1N is implemented) when MOE=0 1: OC1=1 (after a dead-time if OC1N is implemented) when MOE=0 Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BKR register).
7	TI1S	rw	0x00	TI1 selection 0: The TIMx_CH1 pin is connected to TI1 input 1: The TIMx_CH1, CH2 and CH3 pins are connected to the TI1 input (XOR combination)

Bit	Field	Type	Reset	Description
6: 4	MMS	rw	0x00	Master mode selection These bits allow to select the information to be sent in master mode to slave timers for synchronization (TRGO). The combination is as follows: 000: Reset - the UG bit from the TIMx_EGR register is used as trigger output (TRGO). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on TRGO is delayed compared to the actual reset. 001: Enable - the Counter Enable signal CNT_EN is used as trigger output (TRGO). It is useful to start several timers at the same time or to control a window in which a slave timer is enable. The Counter Enable signal is generated by a logic OR between CEN control bit and the trigger input when configured in gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on TRGO, except if the master/slave mode is selected (see the MSM bit description in TIMx_SMCR register). 010: Update - The update event is selected as trigger output (TRGO). For instance, a master timer can then be used as a prescaler for a slave timer. 011: Compare Pulse - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred (TRGO). 100: Compare - OC1REF signal is used as trigger output (TRGO) 101: Compare - OC2REF signal is used as trigger output (TRGO) 110: Compare - OC3REF signal is used as trigger output (TRGO) 111: Compare - OC4REF signal is used as trigger output (TRGO)
3	CCDS	rw	0x00	Capture/compare DMA selection 0: CCx DMA request sent when CCx event occurs 1: CCx DMA requests sent when update event occurs

Bit	Field	Type	Reset	Description
2	CCUS	rw	0x00	Capture/compare control update selection 0: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COM bit only 1: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COM bit or when an rising edge occurs on TRGI Note: This bit acts only on channels that have a complementary output.
1	Reserved			Reserved, always read as 0.
0	CCPC	rw	0x00	Capture/compare preloaded control 0: CCxE, CCxNE and OCxM bits are not preloaded 1: CCxE, CCxNE and OCxM bits are preloaded, after having been written, they are updated only when a commutation event (COM) occurs (COMG bit set). Note: This bit acts only on channels that have a complementary output.

11.4.3 Slave mode control register(TIMx_SMCR)

Offset address: 0x08

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ETP	ECE	ETPS		ETF				MSM	TS			Res.	SMS		
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		rw	rw	rw

Bit	Field	Type	Reset	Description
15	ETP	rw	0x00	External trigger polarity This bit selects whether ETR or inverted ETR is used for trigger operations. 0: ETR is non-inverted, active at high level or rising edge. 1: ETR is inverted, active at low level or falling edge.

Bit	Field	Type	Reset	Description
14	ECE	rw	0x00	External clock enable This bit enables External clock mode 2. 0: External clock mode 2 disabled 1: External clock mode 2 enabled. The counter is clocked by any active edge on the ETRF signal. Note 1: Setting the ECE bit has the same effect as selecting external clock mode 1 with TRGI connected to ETRF (SMS=111 and TS=111). Note 2: It is possible to simultaneously use external clock mode 2 with the following slave modes: reset mode, gated mode and trigger mode. Nevertheless, TRGI must not be connected to ETRF in this case (TS bits must not be 111). Note 3: If external clock mode 1 and external clock mode 2 are enabled at the same time, the external clock input is ETRF.
13: 12	ETPS	rw	0x00	External trigger prescaler External trigger signal ETRP frequency must be at most 1/4 of TIMxCLK frequency. A prescaler can be enabled to reduce ETRP frequency. It is useful when inputting fast external clocks. 00: Prescaler OFF 01: ETRP frequency divided by 2 10: ETRP frequency divided by 4 11: ETRP frequency divided by 8

Bit	Field	Type	Reset	Description
11: 8	ETF	rw	0x00	External trigger filter This bit-field then defines the frequency used to sample ETRP signal and the length of the digital filter applied to ETRP. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output: 0000: No filter, sampling is done at f_{DTS}. 0001: sampling frequency $f_{SAMPLING}=f_{CK\_INT}$, N = 2 0010: sampling frequency $f_{SAMPLING}=f_{CK\_INT}$, N = 4 0011: sampling frequency $f_{SAMPLING}=f_{CK\_INT}$, N = 8 0100: sampling frequency $f_{SAMPLING}=f_{DTS}/2$, N = 6 0101: sampling frequency $f_{SAMPLING}=f_{DTS}/2$, N = 8 0110: sampling frequency $f_{SAMPLING}=f_{DTS}/4$, N = 6 0111: sampling frequency $f_{SAMPLING}=f_{DTS}/4$, N = 8 1000: sampling frequency $f_{SAMPLING}=f_{DTS}/8$, N = 6 1001: sampling frequency $f_{SAMPLING}=f_{DTS}/8$, N = 8 1010: sampling frequency $f_{SAMPLING}=f_{DTS}/16$, N = 5 1011: sampling frequency $f_{SAMPLING}=f_{DTS}/16$, N = 6 1100: sampling frequency $f_{SAMPLING}=f_{DTS}/16$, N = 8 1101: sampling frequency $f_{SAMPLING}=f_{DTS}/32$, N = 5 1110: sampling frequency $f_{SAMPLING}=f_{DTS}/32$, N = 6 1111: sampling frequency $f_{SAMPLING}=f_{DTS}/32$, N = 8
7	MSM	rw	0x00	Master/slave mode 0: No action 1: The effect of an event on the trigger input (TRGI) is delayed to allow a perfect synchronization between the current timer and its slaves (through TRGO). It is useful if we want to synchronize several timers on a single external event.

Bit	Field	Type	Reset	Description
6: 4	TS	rw	0x00	Trigger selection This bit-field selects the trigger input to be used to synchronize the counter. 000: Internal Trigger 0 (ITR0) 001: Internal Trigger 1(ITR1) 010: Internal Trigger 2(ITR2) 011: Internal Trigger 3(ITR3) 100: TI1 Edge Detector (TI1F_ED) 101: Filtered Timer Input 1 (TI1FP1) 110: Filtered Timer Input 2(TI2FP2) 111: External Trigger input (ETRF) See the following table for more details on ITRx. Note: These bits must be changed only when they are not used (e.g. when SMS=000) to avoid wrong edge detections at the transition.
3	Reserved			Reserved, always read as 0.

Bit	Field	Type	Reset	Description
2: 0	SMS	rw	0x00	Slave mode selection When external signals are selected the active edge of the trigger signal (TRGI) is linked to the polarity selected on the external input (refer to Input Control register and Control Register description). 000: Slave mode disabled - if CEN = '1' then the prescaler is clocked directly by the internal clock. 001: Encoder mode 1 - Counter counts up/down on TI2FP1 edge depending on TI1FP2 level. 010: Encoder mode 2 - Counter counts up/down on TI1FP2 edge depending on TI2FP1 level. 011: Encoder mode 3 - Counter counts up/down on both TI1FP1 and TI2FP2 edges depending on the level of the other input. 100: Reset Mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter and generates an update of the registers. 101: Gated Mode - The counter clock is enabled when the trigger input (TRGI) is high. The counter stops (but is not reset) as soon as the trigger input becomes low. Both start and stop of the counter are controlled. 110: Trigger Mode - The counter starts at a rising edge of the trigger TRGI (but it is not reset). Only the start of the counter is controlled. 111: External Clock Mode 1 - Rising edges of the selected trigger input (TRGI) clock the counter. Note: The gated mode must not be used if TI1F_EN is selected as the trigger input (TS= '100'). Indeed, TI1F_ED outputs 1 pulse for each transition on TI1F, whereas the gated mode checks the level of the trigger signal.

10	CC2OF	rc_w0	0x00	Capture/Compare 2 overcapture flag Refer to CC1OF description.
9	CC1OF	rc_w0	0x00	Capture/Compare 1 overcapture flag This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to ‘0’. 0: No overcapture has been detected. 1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set.
8	Reserved			Reserved, always read as 0.
7	BIF	rc_w0	0x00	Break interrupt flag This flag is set by hardware as soon as the break input goes active. It can be cleared by software if the break input is not active. 0: No break event occurred. 1: An active level has been detected on the break

Bit	Field	Type	Reset	Description
6	TIF	rc_w0	0x00	Trigger interrupt flag This flag is set by hardware on trigger event (active edge detected on TRGI input when the slave mode controller is enabled in all modes but gated mode, both edges in case gated mode is selected). It is cleared by software. 0: No trigger event occurred. 1: Trigger interrupt pending.
5	COMIF	rc_w0	0x00	COM interrupt flag This flag is set by hardware on COM event (when Capture/compare Control bits - CCxE, CCxNE, OCxM - have been updated). It is cleared by software. 0: No COM event occurred. 1: COM interrupt pending.
4	CC4IF	rc_w0	0x00	Capture/Compare 4 interrupt flag Refer to CC1IF description.
3	CC3IF	rc_w0	0x00	Capture/Compare 3 interrupt flag Refer to CC1IF description.
2	CC2IF	rc_w0	0x00	Capture/Compare 2 interrupt flag Refer to CC1IF description.
1	CC1IF	rc_w0	0x00	Capture/Compare 1 interrupt flag If channel CC1 is configured as output: This flag is set by hardware when the counter matches the compare value, with some exception in center-aligned mode (refer to the CMS bits in the TIMx_CR1 register description). It is cleared by software. 0: No match 1: The content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register. If channel CC1 is configured as input: This bit is set by hardware on a capture. It is cleared by software or by reading the TIMx_CCR1 register. 0: No input capture occurred 1: The counter value has been captured in TIMx_CCR1 register (An edge has been detected on IC1 which matches the selected polarity)

Bit	Field	Type	Reset	Description
0	UIF	rc_w0	0x00	Update interrupt flag This bit is set by hardware on an update event. It is cleared by software. 0: No update occurred. 1: Update interrupt pending. This bit is set by hardware when the registers are updated: - At overflow or underflow regarding the repetition counter value (update if repetition counter= 0) and if the UDIS=0 in the TIMx_CR1 register. - When CNT is reinitialized by software using the UG bit in TIMx_EGR register, if URS=0 and UDIS=0 in the TIMx_CR1 register. -When CNT is reinitialized by a trigger event (refer to the description of synchronization control register), if URS=0 and UDIS=0 in the TIMx_CR1 register.

11.4.6 Event generation register (TIMx_EGR)

Offset address: 0x14

Bit	Field	Type	Reset	Description
15: 8	Reserved			Reserved, always read as 0.
7	BG	w	0x00	Break generation This bit is set by software in order to generate an event, it is automatically cleared by hardware. 0: No action 1: A break event is generated. MOE bit is cleared and BIF flag is set. Related interrupt or DMA transfer can occur if enabled.
6	TG	w	0x00	Trigger generation This bit is set by software in order to generate an event, it is automatically cleared by hardware. 0: No action 1: The TIF flag is set in TIMx_SR register. Related interrupt or DMA transfer can occur if enabled.

Bit	Field	Type	Reset	Description
5	COMG	w	0x00	Capture/Compare control update generation This bit can be set by software, it is automatically cleared by hardware. 0: No action 1: When CCPC bit is set, it allows to update CCxE, CCxNE and OCxM bits Note: This bit acts only on channels having a complementary output.
4	CC4G	w	0x00	Capture/Compare 4 generation Refer to CC1G description.
3	CC3G	w	0x00	Capture/Compare 3 generation Refer to CC1G description.
2	CC2G	w	0x00	Capture/Compare 2 generation Refer to CC1G description.
1	CC1G	w	0x00	Capture/Compare 1 generation This bit is set by software in order to generate an event, it is automatically cleared by hardware. 0: No action 1: A capture/compare event is generated on channel CC1 If channel CC1 is configured as output: CC1IF flag is set, Corresponding interrupt or DMA request is sent if enabled. If channel CC1 is configured as input: The current value of the counter is captured in TIMx_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.
0	UG	w	0x00	Update generation This bit can be set by software, it is automatically cleared by hardware. 0: No action 1: Reinitialize the counter and generate an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler factor is not affected). The counter is cleared if the center-aligned mode is selected or if DIR=0 (upcounting), otherwise, it takes the auto-reload value (TIMx_ARR) if DIR=1 (downcounting).

11.4.7 Capture/compare mode register 1 (TIMx_CCMR1)

Offset address: 0x18

Reset value: 0x0000

The channels can be used in input (capture mode) or in output (compare mode). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode. For a given bit, OCxx describes its function when the channel is configured in output, ICxx describes its function when the channel is configured in input. So the user must take care that the same bit can have a different meaning for the input stage and for the output stage.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OC2CE	OC2M			OC2PE	OC2FE	CC2S		OC1CE	OC1M			OC1PE	OC1FE	CC1S	
IC2F				IC2PSC				IC1F				IC1PSC			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Output compare mode:

Bit	Field	Type	Reset	Description
15	OC2CE	rw	0x00	Output compare 2 clear enable
14: 12	OC2M	rw	0x00	Output compare 2 mode
11	OC2PE	rw	0x00	Output compare 2 preload enable
10	OC2FE	rw	0x00	Output compare 4 fast enable
9: 8	CC2S	rw	0x00	Capture/Compare 2 selection This bit-field defines the direction of the channel (input/output) as well as the input pin. 00: CC2 channel is configured as output 01: CC2 channel is configured as input, IC2 is mapped on TI2 10: CC2 channel is configured as input, IC2 is mapped on TI1 11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through the TS bit (TIMx_SMCR register) Note: CC2S bits are writable only when the channel is OFF (CC2E = ‘0’ in TIMx_CCER).
7	OC1CE	rw	0x00	Output compare 1 clear enable 0: OC1Ref is not affected by the ETRF Input 1: OC1Ref is cleared as soon as a High level is detected on ETRF input

Bit	Field	Type	Reset	Description
6: 4	OC1M	rw	0x00	Output compare 1 mode These bits define the behavior of the output reference signal OC1REF from which OC1 and OC1N are derived. OC1REF is active high whereas OC1 and OC1N active level depends on CC1P and CC1NP bits. 000: Frozen - The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs 001: Set channel 1 to active level on match. OC1REF signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1). 010: Set channel 1 to inactive level on match. OC1REF signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1). 011: Toggle - OC1REF toggles when TIMx_CNT=TIMx_CCR1. 100: Force inactive level - OC1REF is forced low. 101: Force active level - OC1REF is forced high. 110: PWM mode 1 - In upcounting, channel 1 is active as long as TIMx_CNT<TIMx_CCR1 otherwise inactive. In downcounting, channel 1 is inactive (OC1REF=‘0’) as long as TIMx_CNT>TIMx_CCR1 otherwise active (OC1REF=’1’). 111: PWM mode 2 - In upcounting, channel 1 is inactive as long as TIMx_CNT<TIMx_CCR1otherwise active. In downcounting, channel 1 is active as long as TIMx_CNT>TIMx_CCR1 otherwise inactive. Note 1: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S=’00’(the channel is configured in output). Note 2: In PWM mode 1 or 2, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from “frozen” mode to “PWM” mode.

Bit	Field	Type	Reset	Description
3	OC1PE	rw	0x00	Output compare 1 preload enable 0: Preload register on TIMx_CCR1 disabled. TIMx_CCR1 can be written at anytime, the new value is taken in account immediately. 1: Preload register on TIMx_CCR1 enabled. Read/Write operations access the preload register. TIMx_CCR1 preload value is loaded in the active register at each update event. Note 1: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S=’00’ (the channel is configured in output). Note 2: The PWM mode can be used without validating the preload register only in one pulse mode (OPM bit set in TIMx_CR1 register). Else the behavior is not guaranteed.
2	OC1FE	rw	0x00	Output compare 1 fast enable This bit is used to accelerate the effect of an event on the trigger in input on the CC output. 0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles. 1: An active edge on the trigger input acts like a compare match on CC1 output. Then, OC is set to the compare level independently from the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OCFE acts only if the channel is configured in PWM1 or PWM2 mode.
1: 0	CC1S	rw	0x00	Capture/Compare 1 selection This bit-field defines the direction of the channel (input/output) as well as the input pin. 00: CC1 channel is configured as output 01: CC1 channel is configured as input, IC1 is mapped on TI1 10: CC1 channel is configured as input, IC1 is mapped on TI2 11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register) Note: CC1S bits are writable only when the channel is OFF (CC1E = ’0’ in TIMx_CCER).

Input capture mode:

Bit	Field	Type	Reset	Description
15: 12	IC2F	rw	0x00	Input capture 2 filter
11: 10	IC2PSC	rw	0x00	Input capture 2 prescaler
9: 8	CC2S	rw	0x00	Capture/Compare 2 selection This bit-field defines the direction of the channel (input/output) as well as the input pin. 00: CC2 channel is configured as output 01: CC2 channel is configured as input, IC2 is mapped on TI2 10: CC2 channel is configured as input, IC2 is mapped on TI1 11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through the TS bit (TIMx_SMCR register) Note: CC2S bits are writable only when the channel is OFF (CC2E = '0' in TIMx_CCER).
7: 4	IC1F	rw	0x00	Input capture 1 filter This bit-field defines the frequency used to sample TI1 input and the length of the digital filter applied to TI1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output: 0000: No filter, sampling is done at f_{DTS} 1000: sampling frequency $f_{SAMPLING}=f_{DTS}/8$, N = 6 0001: sampling frequency $f_{SAMPLING}=f_{CK\_INT}$, N = 2 1001: sampling frequency $f_{SAMPLING}=f_{DTS}/8$, N = 8 0010: sampling frequency $f_{SAMPLING}=f_{CK\_INT}$, N = 4 1010: sampling frequency $f_{SAMPLING}=f_{DTS}/16$, N = 5 0011: sampling frequency $f_{SAMPLING}=f_{CK\_INT}$, N = 8 1011: sampling frequency $f_{SAMPLING}=f_{DTS}/16$, N = 6 0100: sampling frequency $f_{SAMPLING}=f_{DTS}/2$, N = 6 1100: sampling frequency $f_{SAMPLING}=f_{DTS}/16$, N = 8 0101: sampling frequency $f_{SAMPLING}=f_{DTS}/2$, N = 8 1101: sampling frequency $f_{SAMPLING}=f_{DTS}/32$, N = 5 0110: sampling frequency $f_{SAMPLING}=f_{DTS}/4$, N = 6 1110: sampling frequency $f_{SAMPLING}=f_{DTS}/32$, N = 6 0111: sampling frequency $f_{SAMPLING}=f_{DTS}/4$, N = 8 1111: sampling frequency $f_{SAMPLING}=f_{DTS}/32$, N = 8

Bit	Field	Type	Reset	Description
3: 2	IC1PSC	rw	0x00	Input capture 1 prescaler This bit-field defines the factor of the prescaler acting on CC1 input (IC1). The prescaler is reset as soon as CC1E=’0’(TIMx_CCER register). 00: no prescaler, capture is done each time an edge is detected on the capture input. 01: capture is done once every 2 events 10: capture is done once every 4 events 11: capture is done once every 8 events
1: 0	CC1S	rw	0x00	Capture/compare 1 selection This bit-field defines the direction of the channel (input/output) as well as the input pin. 00: CC1 channel is configured as output 01: CC1 channel is configured as input, IC1 is mapped on TI1 10: CC1 channel is configured as input, IC1 is mapped on TI2 11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through the TS bit (TIMx_SMCR register) Note: CC1S bits are writable only when the channel is OFF (CC1E = ‘0’ in TIMx_CCER).

11.4.8 Capture/compare mode register 2(TIMx_CCMR2)

Offset address: 0x1C

Reset value: 0x0000

Refer to the above CCMR1 register description.

7	CC2NP	rw	0x00	Capture/Compare 2 complementary output polarity Refer to CC1NP description.
6	CC2NE	rw	0x00	Capture/Compare 2 complementary output enable Refer to CC1NE description.
5	CC2P	rw	0x00	Capture/Compare 2 output polarity Refer to CC1P description.
4	CC2E	rw	0x00	Capture/Compare 2 output enable Refer to CC1E description.
3	CC1NP	rw	0x00	Capture/Compare 1 complementary output polarity 0: OC1N active high 1: OC1N active low Note: This bit is not modified as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S=”00” (the channel is configured in output).
2	CC1NE	rw	0x00	Capture/Compare 1 complementary output enable 0: Off - OC1N is not active. OC1N level is then function of MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits. 1: On - OC1N signal is output on the corresponding output pin depending on MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.
1	CC1P	rw	0x00	Capture/Compare 1 output polarity CC1 channel is configured as output: 0: OC1 active high 1: OC1 active low CC1 channel is configured as input: This bit selects whether IC1 or inverted IC1 is used for trigger or capture operations. 0: non-inverted: capture is done on a rising edge of IC1. When used as external trigger, IC1 is non-inverted. 1: inverted: capture is done on a falling edge of IC1. When used as external trigger, IC1 is inverted

Bit	Field	Type	Reset	Description
0	CC1E	rw	0x00	Capture/Compare 1 output enable CC1 channel is configured as output: 0: Off - OC1 is not active. OC1 level is then function of MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits. 1: On - OC1 signal is output on the corresponding output pin depending on MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits. CC1 channel is configured as input: This bit determines if a capture of the counter value can actually be done into the input capture/compare register 1 (TIMx_CCR1) or not. 0: Capture disabled. 1: Capture enabled.

Table 40. Output Control Bits for Complementary OCx and OCxN Channels with Break Feature

Control bits					Output states(1)	
MOE bit	**OSSI bit**	**OSSR bit**	**CCxE bit**	**CCxNE bit**	**OCx output state**	**OCxN output state**
1	X	0	0	0	Output Disabled (not driven by the timer), OCx = 0, OCx_EN = 0	Output Disabled (not driven by the timer), OCxN = 0, OCxN_EN = 0
		0	0	1	Output Disabled (not driven by the timer), OCx = 0, OCx_EN = 0	OCxREF + Polarity, OCxN = OCxREF xor CCxNP, OCxN_EN = 1
		0	1	0	OCxREF + Polarity, OCx = OCxREF xor CCxP, OCx_EN = 1	Output Disabled (not driven by the timer), OCxN = 0, OCxN_EN = 0
		0	1	1	OCREF + Polarity + dead-time, OCx_EN = 1	OCxREF (inverted) + Polarity + dead-time, OCxN_EN = 1
		1	0	0	Output Disabled (not driven by the timer), OCx = CCxP, OCx_EN = 0	Output Disabled (not driven by the timer), OCxN = CCxNP, OCxN_EN = 0
		1	0	1	Off-State (output enabled with inactive state) OCx = CCxP, OCx_EN = 1	OCxREF + Polarity, OCxN = OCxREF xor CCxNP, OCxN_EN = 1
		1	1	0	OCxREF + Polarity, OCx = OCxREF xor CCxP, OCx_EN = 1	Off-State (output enabled with inactive state), OCxN = CCxNP, OCxN_EN = 1
		1	1	1	OCxREF + Polarity + dead-time, OCx_EN = 1	OCxREF (inverted) + Polarity + dead-time, OCxN_EN = 1
0	0	X	0	0	Output Disabled (not driven by the timer)	
	0		0	1	Asynchronously: OCx=CCxP, OCx_EN=0, OCxN=CCxNP,	
	0		1	0	OCxN_EN = 0;	
	0		1	1	Then if the clock is present:after a dead-time OCx = OISx , OCxN = OISxN, Assuming that OISx and OISxN do not correspond to OCX and OCxN in active state.	
	1		0	0	Off-State (output enabled with inactive state)	
	1		0	1	Asynchronously: OCx = CCxP, OCx_EN = 1, OCxN = CCxNP,	
	1		1	0	OCxN_EN = 1;	
	1		1	1	Then if the clock is present:after a dead-time OCx = OISx , OCxN = OISxN, Assuming that OISx and OISxN do not correspond to OCX and OCxN in active state.	

1. When both outputs of a channel are not used (CCxE = CCxNE = 0), the OISx, OISxN, CCxP and CCxNP bits must be kept cleared.

Note 1: The state of the external I/O pins connected to the complementary OCx and OCxN channels depends on the OCx and OCxN channel state and the GPIO registers.

2: In case of CCxE=0 and CCxNE=0, OCx and OCxN are in high impedance state after output is disabled.

11.4.10 Counter(TIMx_CNT)

Offset address: 0x24

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CNT															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit	Field	Type	Reset	Description
15: 0	CNT	rw	0x0000	Counter value

11.4.11 Prescaler(TIMx_PSC)

Offset address: 0x28

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PSC															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit	Field	Type	Reset	Description
15: 0	PSC	rw	0x0000	Prescaler value The counter clock frequency (CK_CNT) is equal to f_{CK_PSC} /(PSC + 1). PSC contains the value to be loaded in the active prescaler register at each update event (including when the counter is cleared through UG bit of TIMx_EGR register or through trigger controller when configured in ”reset mode”)

11.4.12 Auto-reload register(TIMx_ARR)

Offset address: 0x2C

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ARR															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit	Field	Type	Reset	Description
15: 0	ARR	rw	0x0000	Prescaler value ARR is the value to be loaded in the actual auto-reload register. Refer to section 11.3.1 for more details about ARR update and behavior. The counter is blocked while the auto-reload value is null.

11.4.13 Repetition counter register(TIMx_RCR)

Offset address: 0x30

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								REP							
								rw	rw	rw	rw	rw	rw	rw	rw

Bit	Field	Type	Reset	Description
15: 8	Reserved			Reserved, always read as 0.
7: 0	REP	rw	0x00	Repetition counter value These bits allow the user to set-up the update rate of the compare registers (i.e. periodically transfers from preload to active registers) when preload registers are enabled, as well as the update interrupt generation rate, if this interrupt is enabled. Each time the REP_CNT related downcounter reaches zero, an update event is generated and it restarts counting from REP value. As REP_CNT is reloaded with REP value only at the repetition update event U_RC, any write to the TIMx_RCR register is not taken in account until the next repetition update event. It means in PWM mode (REP + 1) corresponds to: - the number of PWM periods in edge-aligned mode - number of half PWM period in center-aligned mode

11.4.14 Capture/compare register 1(TIMx_CCR1)

Offset address: 0x34

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CCR1															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit	Field	Type	Reset	Description
15: 0	CCR1	rw	0x0000	Capture/Compare 1 value If CC1 channel is configured as output: CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value). The written value is transferred to the current register immediately if the preload feature is not selected in the TIMx_CCMR1 register (bit OC1PE). Otherwise the preload value is copied in the active capture/compare 1 register when an update event occurs. The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on OC1 output. If CC1 channel is configured as input: CCR1 contains the counter value transferred by the last input capture 1 event (IC1).

11.4.15 Capture/compare register2(TIMx_CCR2)

Offset address: 0x38

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CCR2															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit	Field	Type	Reset	Description
15: 0	CCR2	rw	0x0000	Capture/Compare 2 value If CC2 channel is configured as output: CCR2 contains the value to be loaded in the actual capture/compare 2 register (preload value). The written value is transferred to the current register immediately if the preload feature is not selected in the TIMx_CCMR2 register (bit OC2PE). Otherwise the preload value is copied in the active capture/compare 2 register when an update event occurs. The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on OC2 output. If CC2 channel is configured as input: CCR2 contains the counter value transferred by the last input capture 2 event (IC2).

11.4.16 Capture/compare register 3(TIMx_CCR3)

Offset address: 0x3C

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CCR3															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit	Field	Type	Reset	Description
15: 0	CCR3	rw	0x0000	Capture/Compare 3 value If CC3 channel is configured as output: CCR3 contains the value to be loaded in the actual capture/compare 3 register (preload value). The written value is transferred to the current register immediately if the preload feature is not selected in the TIMx_CCMR3 register (bit OC3PE). Otherwise the preload value is copied in the active capture/compare 3 register when an update event occurs. The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on OC3 output. If CC3 channel is configured as input: CCR3 contains the counter value transferred by the last input capture 3 event (IC3).

11.4.17 Capture/compare register 4(TIMx_CCR4)

Offset address: 0x40

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CCR4															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit	Field	Type	Reset	Description
15: 0	CCR4	rw	0x0000	Capture/Compare 4 value If CC4 channel is configured as output: CCR4 contains the value to be loaded in the actual capture/compare 4 register (preload value). The written value is transferred to the current register immediately if the preload feature is not selected in the TIMx_CCMR4 register (bit OC4PE). Otherwise the preload value is copied in the active capture/compare 4 register when an update event occurs. The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on OC4 output. If CC4 channel is configured as input: CCR4 contains the counter value transferred by the last input capture 4 event (IC4).

11.4.18 Break and dead-time register(TIMx_BDTR)

Offset address: 0x44

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MOE	AOE	BKP	BKE	OSSR	OSSI	LOCK		DTG							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Note: As the bits AOE, BKP, BKE, OSSI, OSSR and DTG can be write-locked depending on the LOCK configuration, it can be necessary to configure all of them during the first write access to the TIMx_BDTR register.

Bit	Field	Type	Reset	Description
15	MOE	rw	0x00	Main output enable This bit is cleared asynchronously by hardware as soon as the break input is active. It is cleared by software or set automatically, depending on the AOE bit. It is acting only on the channels which are configured in output. 0: OC and OCN outputs are disabled or forced to idle state. 1: OC and OCN outputs are enabled if their respective enable bits are set (CCxE, CCxNE in TIMx_CCER register). See OC/OCN enable description for more details (section 11.4.9: capture/compare enable register).

Bit	Field	Type	Reset	Description
14	AOE	rw	0x00	Automatic output enable 0: MOE can be set only by software 1: MOE can be set by software or automatically at the next update event (if the break input is not be active) Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).
13	BKP	rw	0x00	Break polarity 0: Break input BRK is active low 1: Break input BRK is active high Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).
12	BKE	rw	0x00	Break enable 0: Break inputs (BRK and BRK_ACTH) disabled 1: Break inputs (BRK and BRK_ACTH) enabled Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).
11	OSSR	rw	0x00	Off-state selection for Run mode This bit is used when MOE=1 on channels configured as complementary outputs. OSSR is not implemented if no complementary output is implemented in the timer. See OC/OCN enable description for more details (section 11.4.9: capture/compare enable register (TIMx_CCER)). 0: When inactive, OC/OCN outputs are disabled (OC/OCN enable output signal=0). 1: When inactive, OC/OCN outputs are forced first with their idle level as soon as CCxE=1 or CCxNE=1. Then, set OC/OCN enable output signal=1 Note: This bit can not be modified as long as LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).

Bit	Field	Type	Reset	Description
10	OSSI	rw	0x00	Off-state selection for Idle mode This bit is used when MOE=0 on channels configured as outputs. See OC/OCN enable description for more details (section 11.4.9: capture/compare enable register (TIMx_CCER)). 0: When inactive, OC/OCN outputs are disabled (OC/OCN enable output signal=0). 1: When inactive, OC/OCN outputs are forced first with their idle level as soon as CCxE=1 or CCxNE=1. OC/OCN enable output signal=1 Note: This bit can not be modified as long as LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).
9: 8	LOCK	rw	0x00	Lock configuration These bits offer a write protection against software errors. 00: LOCK OFF - No bit is write protected. 01: LOCK Level 1 = DTG, BKE, BKP, AOE bits in TIMx_BDTR register, and OISx/OISxN bits in TIMx_CR2 register can no longer be written. 10: LOCK Level 2 = LOCK Level 1 + CC Polarity bits (CCxP/CCxNP bits in TIMx_CCER register, as long as the related channel is configured in output through the CCxS bits) as well as OSSR and OSSI bits can no longer be written. 11: LOCK Level 3 = LOCK Level 2 + CC Control bits (OCxM and OCxPE bits in TIMx_CCMRx registers, as long as the related channel is configured in output through the CCxS bits) can no longer be written. Note: The LOCK bits can be written only once after the reset. Once the TIMx_BDTR register has been written, their content is frozen until the next reset.

Bit	Field	Type	Reset	Description
7: 0	DTG	rw	0x00	Dead-time generator setup This bit-field defines the duration of the dead-time inserted between the complementary outputs. It is assumed that DT correspond to this duration. DTG[7: 5] = 0xx: DT = (DTG[7: 0] + 1) × t_{dtg}, t_{dtg} = t_{DTS}; DTG[7: 5] = 10x: DT = (DTG[5: 0] + 1 + 64) × t_{dtg}, t_{dtg} = 2 × t_{DTS}; DTG[7: 5] = 110: DT = (DTG[4: 0] + 1 + 32) × t_{dtg}, t_{dtg} = 8 × t_{DTS}; DTG[7: 5] = 111: DT = (DTG[4: 0] + 1 + 32) × t_{dtg}, t_{dtg} = 16 × t_{DTS}; Example: if t_{DTS} = 125ns(8MHz), dead-time possible values are: 125ns to 15875ns by 125 nS steps; 16μs to 31750ns by 250 nS steps; 32μs to 63μs by 1 μs steps; 64μs to 126μs by 2 μs steps; Note: This bit-field can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

11.4.19 DMA control register(TIMx_DCR)

Offset address: 0x48

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.			DBL					Res.			DBA				
			w	w	w	w	w				w	w	w	w	w

Bit	Field	Type	Reset	Description
15: 13	Reserved			Reserved, always read as 0.

Bit	Field	Type	Reset	Description
12: 8	DBL	w	0x00	DMA burst length This bit field defines the burst transfer in the continuous mode (the timer detects a burst transfer when a write access to the TIMx_DMAR register address is performed), namely, the number of transfers, in half-word (double bytes) or bytes. 00000: 1 transfer 00001: 2 transfers 00010: 3 transfers .... 10001: 18 transfers Example: Let us consider the following transfer: DBL = 7 and DBA = TIM2_CR1. - If DBL =7 and DBA = TIM2_CR1 represent the address of data to be transferred, the transfer address is given by: (Address of TIMx_CR1) + DBA + (DMA index), where, DMA index = DBL TIMx_CR1 address + DBA + 7 is the address of data to be written or read, so that the transfer is completed to/from 7 registers starting from the TIMx_CR1 address + DBA. According to the setting of DMA data length, the following case may occur: -If the data is set to half word (16 bits), the data will be transferred to all 7 registers. -If the data is set to bytes, the data will still be transferred to all 7 registers: the first register contains the first MSB byte, the second register contains the first LSB byte, and so on. Therefore, the user must specify the data width of DMA transfer for the timer.
7: 5	Reserved			Reserved, always read as 0.
4: 0	DBA	w	0x00	DMA base address These bits define the base-address for DMA transfers in the continuous mode (when write access is done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register. 00000: TIMx_CR1 00001: TIMx_CR2 00010: TIMx_SMCR .....

Bit	Field	Type	Reset	Description
15: 0	DMAB	w	0x0000	DMA register for burst accesses A write operation to the TIMx_DMAR register will access the register located at the following address: TIMx_CR1 address + DBA + DMA index, Where: ‘TIMx_CR1 address’ is the address of the control register 1; ‘DBA’ is the DMA base address configured in TIMx_DCR register; ‘DMA index’ is the offset automatically controlled by the DMA transfer, depending on DBL configured in TIMx_DCR.

12 16-bit general-purpose timers (TIMx16 Bit)

16-bit general-purpose timers (TIMx16 Bit)

12.1 TIMx introduction

General-purpose timers consist of a 16-bit auto-reload counter driven by a programmable prescaler.

It may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare and PWM).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

TIMx are completely independent, and do not share any resources. They can be synchronized together as described in Section Timer Synchronization.

12.2 TIMx Main features

TIM3 functions include:

- 16-bit up, down, up/down auto-reload register
- 16-bit programmable prescaler allowing dividing (modifing in real time) the counter clock frequency either by any factor between 1 and 65536.
- Up to 4 independent channels for:
  - Input capture
  - Output compare
  - PWM generation (Edge and Center-aligned Mode)
  - One-pulse mode output
- circuit to control the timer with external signals and to interconnect several timers together.
- Interrupt/DMA generation on the following events:
  - Update: counter overflow/underflow, counter initialization (by software or internal/external trigger)
  - Trigger event (counter start, stop, initialization or count by internal/external trigger)
  - Input capture
  - Output compare
- Supports incremental (quadrature) encoder and hall-sensor circuitry for positioning purposes

- Trigger input for external clock or cycle-by-cycle current management

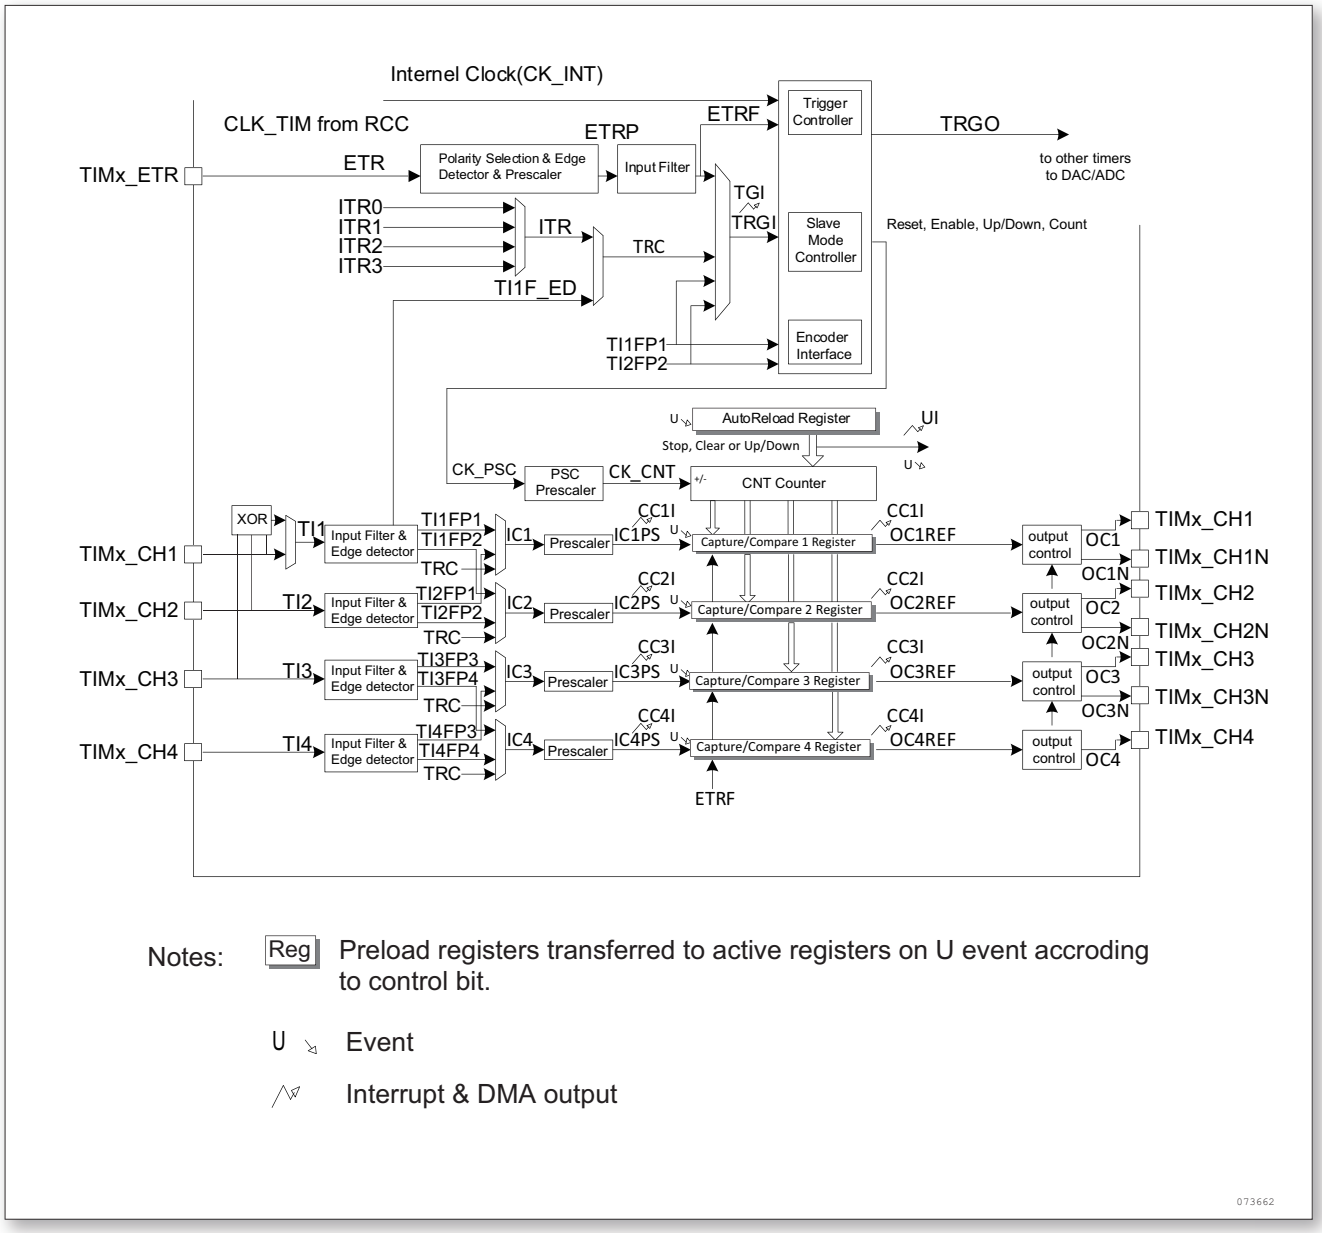

Figure 77. Block Diagram of general-purpose timer

12.3 TIMx Functional description

12.3.1 Time-base unit

The main block of the programmable general-purpose timer is a 16-bit counter with its related auto-reload register. The counter can count up, down or both up and down. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running. The time-base unit includes:

- Counter register (TIMx_CNT)
- Prescaler register (TIMx_PSC)

- Auto-reload register (TIMx_ARR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter reaches the overflow (or underflow when downcounting) and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in details for each configuration.

The counter is clocked by the prescaler output CK_CNT, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler factor is taken into account at the next update event.

The following figures give some examples of the counter behavior when the prescaler factor is changed on the fly:

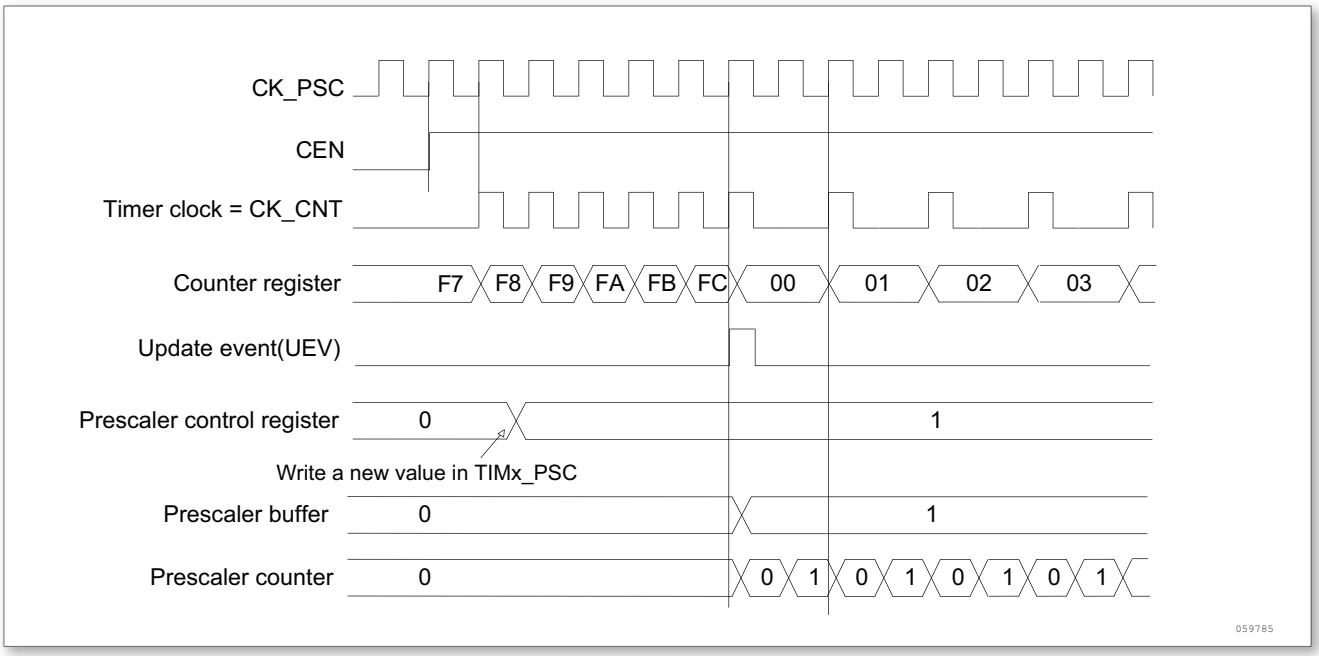

Figure 78. Counter Timing Diagram with Prescaler Division Change from 1 to 2

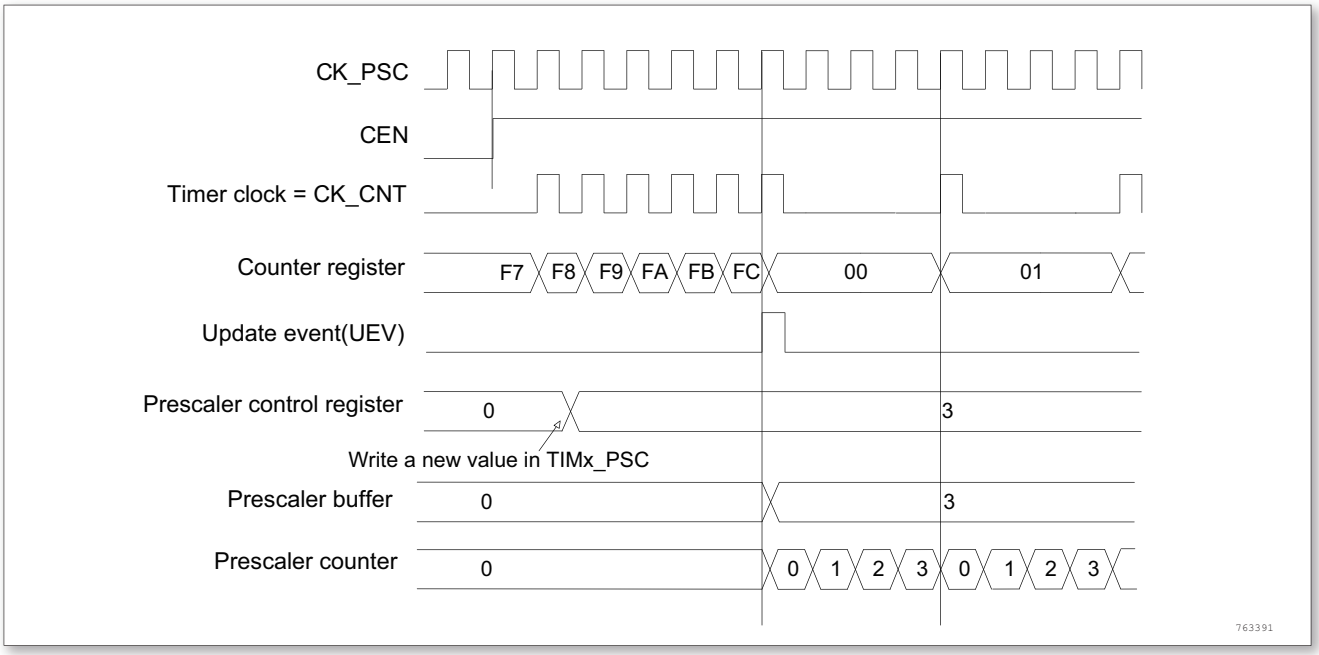

Figure 79. Counter Timing Diagram with Prescaler Division Change from 1 to 4

12.3.2 Counter modes

Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

An Update event can be generated at each counter overflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller).

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change).

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag bit(UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).
- The auto-reload shadow register is updated with the preload value (TIMx_ARR).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR = 0x36.

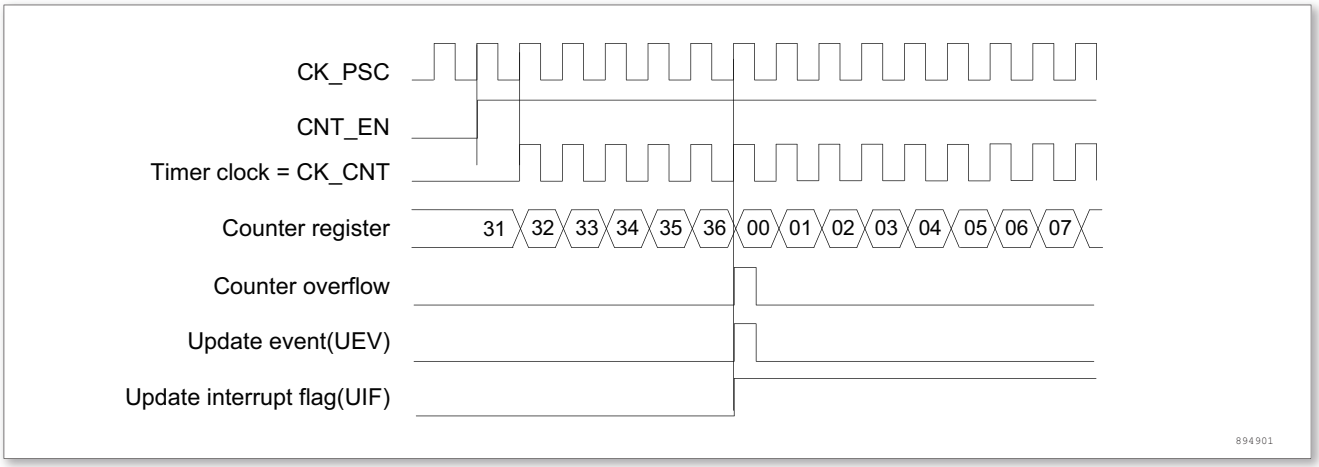

Figure 80. Counter Timing Diagram, Internal Clock Divided by 1

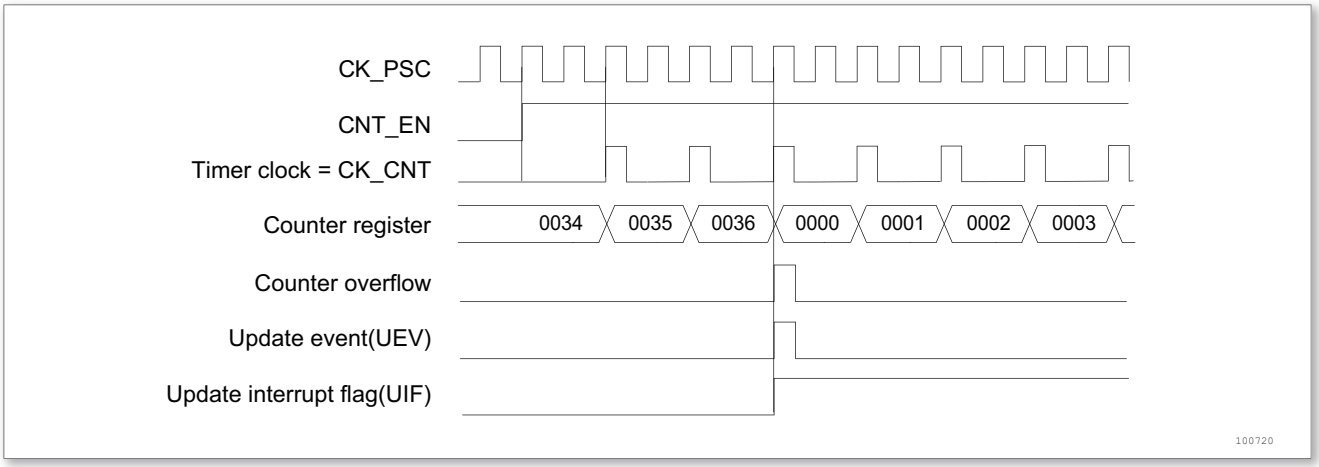

Figure 81. Counter Timing Diagram, Internal Clock Divided by 2

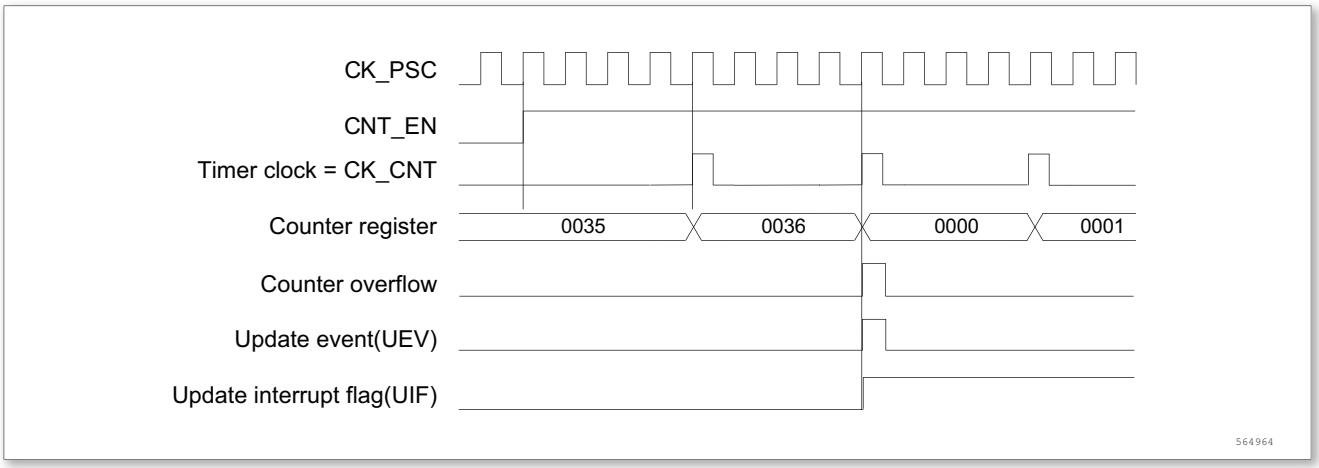

Figure 82. Counter Timing Diagram, Internal Clock Divided by 4

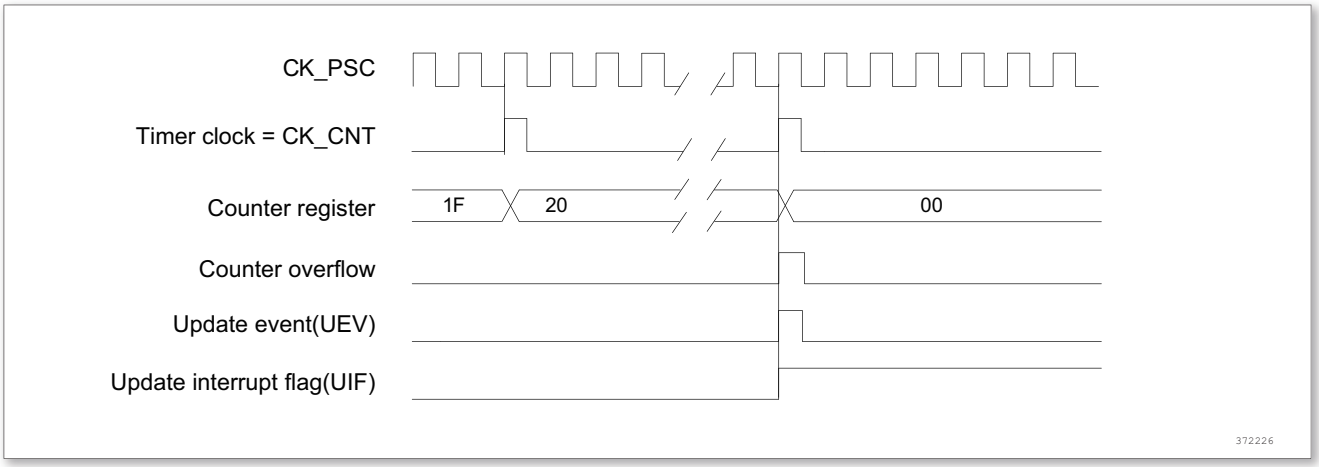

Figure 83. Counter Timing Diagram, Internal Clock Divided by N

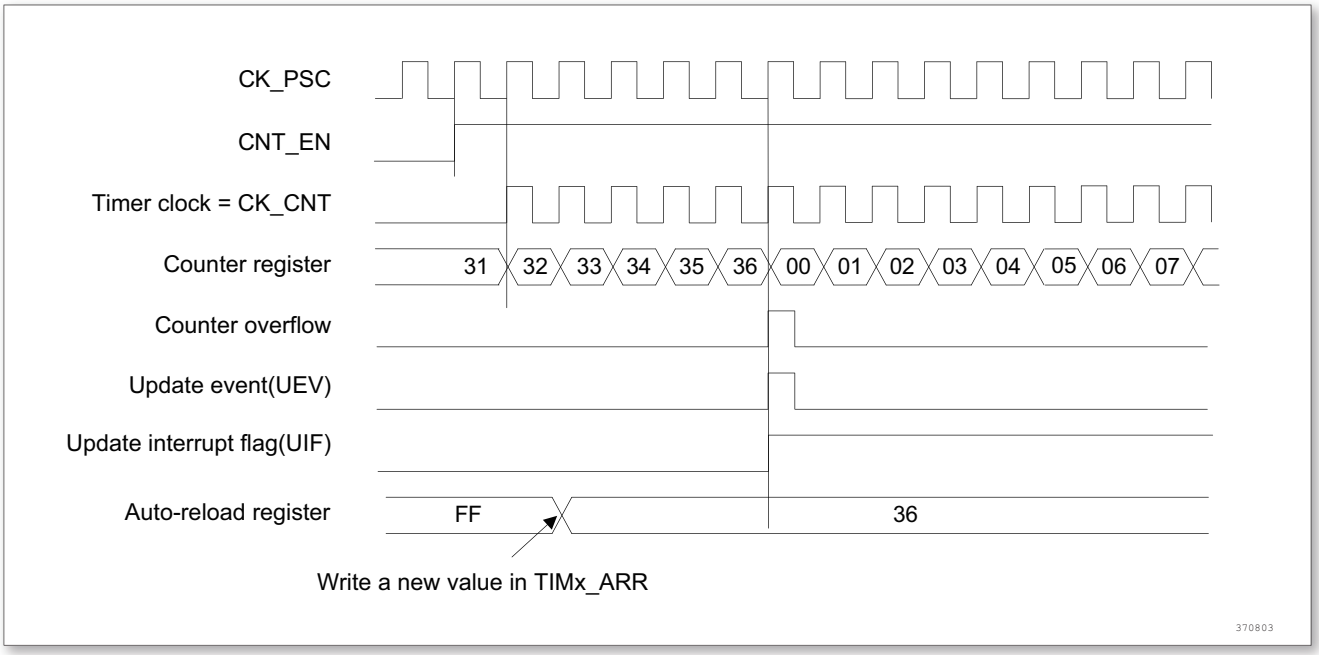

Figure 84. Counter Timing Diagram, Update Event When ARPE = 0 (TiMx_ARR Not Preloaded)

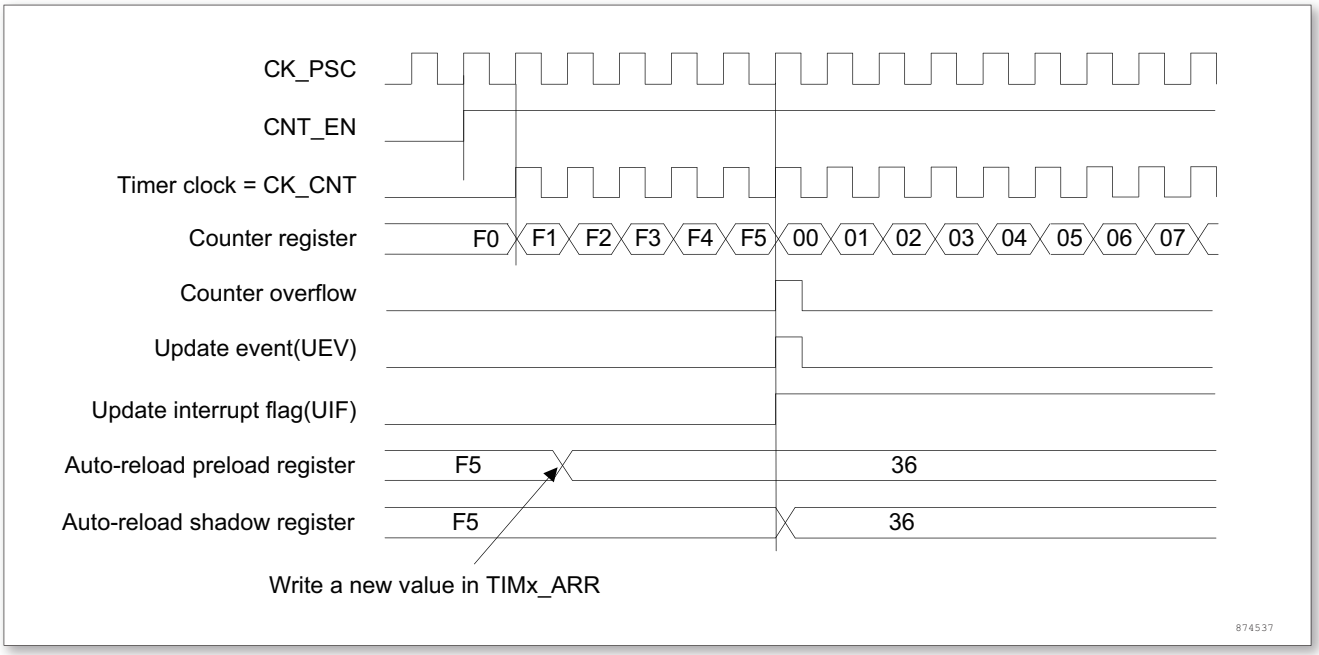

Figure 85. Counter Timing Diagram, Update Event When ARPE = 1 (TiMx_ARR Preloaded)

Downcounting mode

In downcounting mode, the counter counts from the auto-reload value (content of the TIMx_ARR register) down to 0, then restarts from the auto-reload value and generates a counter underflow event.

An Update event can be generated at each counter overflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller).

The UEV update event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter restarts from the current auto-reload value, whereas the counter of the prescaler restarts from 0 (but the prescale rate doesn’t change).

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register).

Note: The auto-reload is updated before the counter is reloaded, so that the next period is the expected one.

The following figures show some examples of the counter behavior for different clock

frequencies when TIMx_ARR = 0x36.

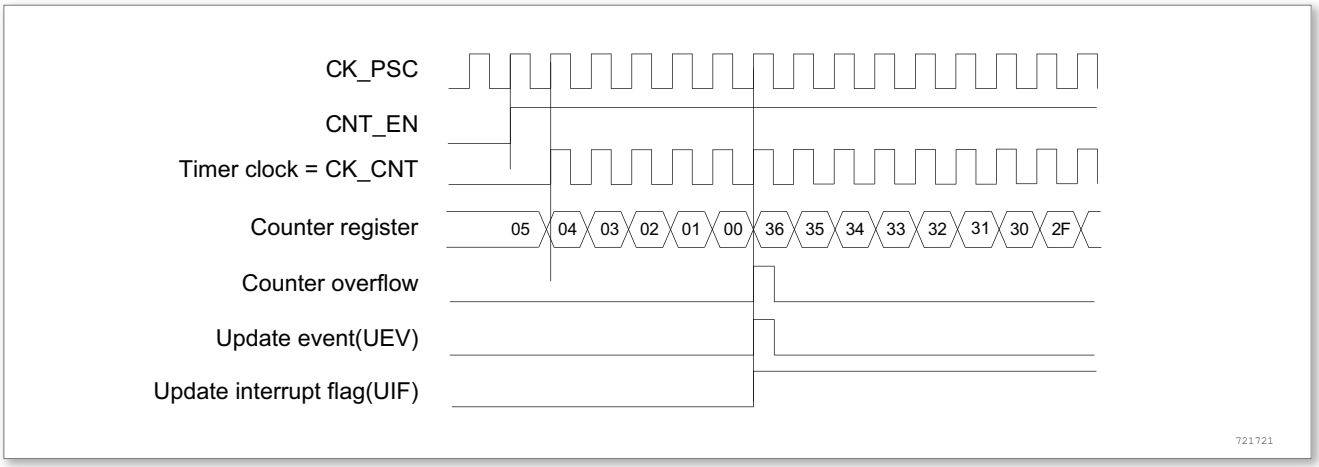

Figure 86. Counter Timing Diagram, Internal Clock Divided by 1

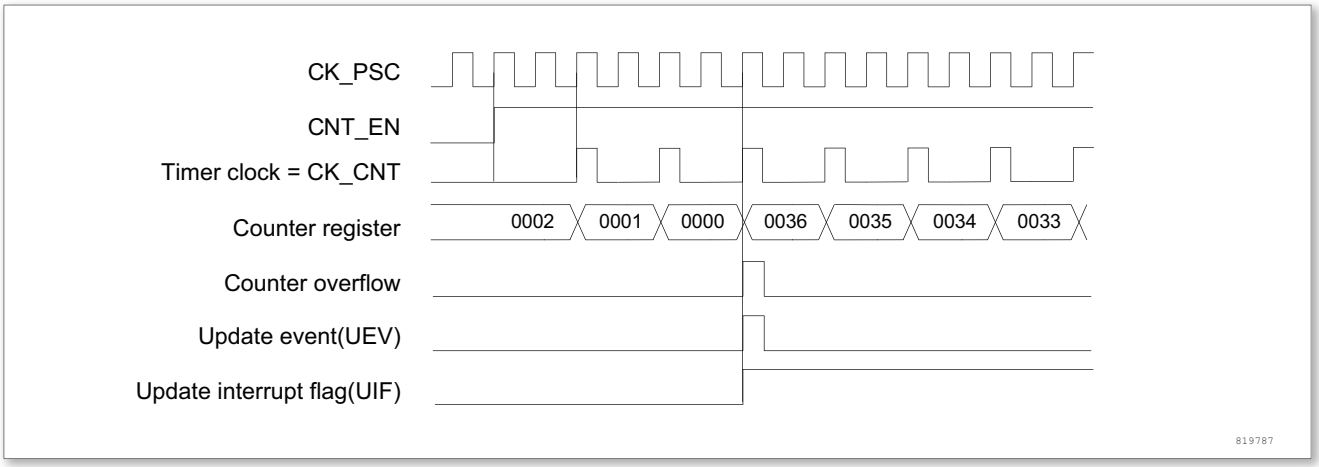

Figure 87. Counter Timing Diagram, Internal Clock Divided by 2

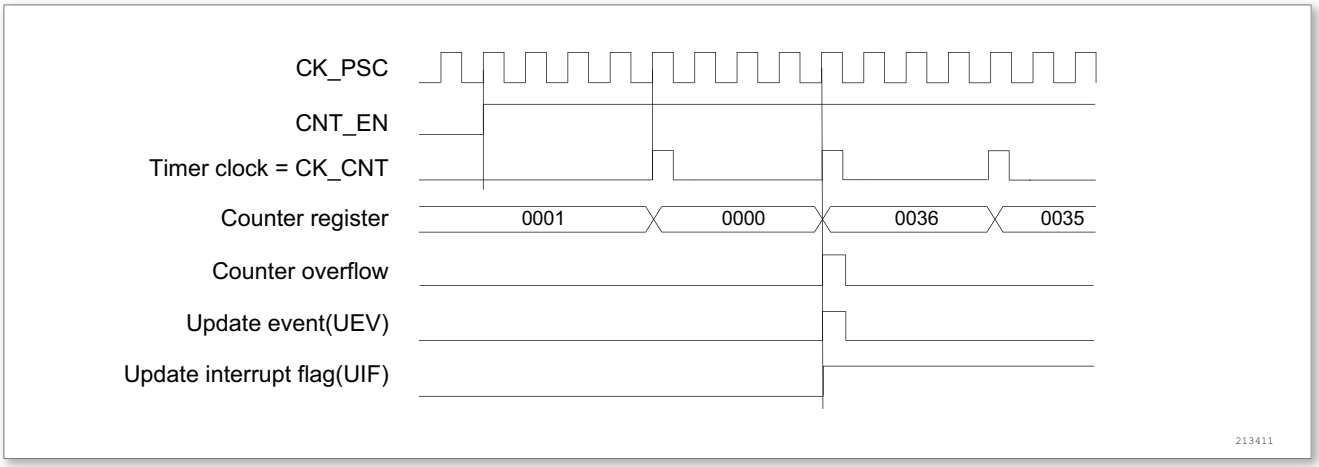

Figure 88. Counter Timing Diagram, Internal Clock Divided by 4

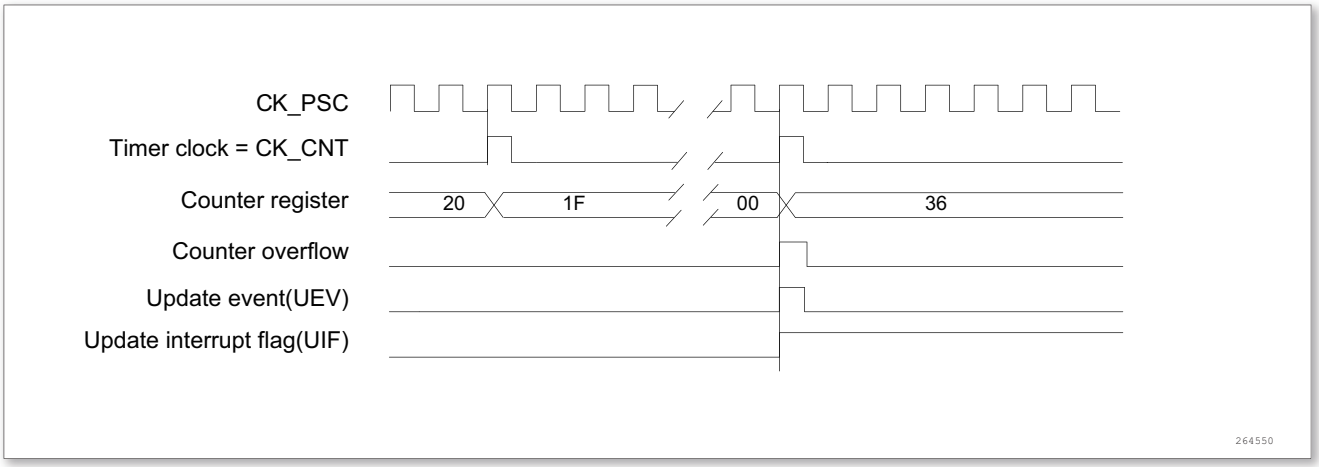

Figure 89. Counter Timing Diagram, Internal Clock Divided by N

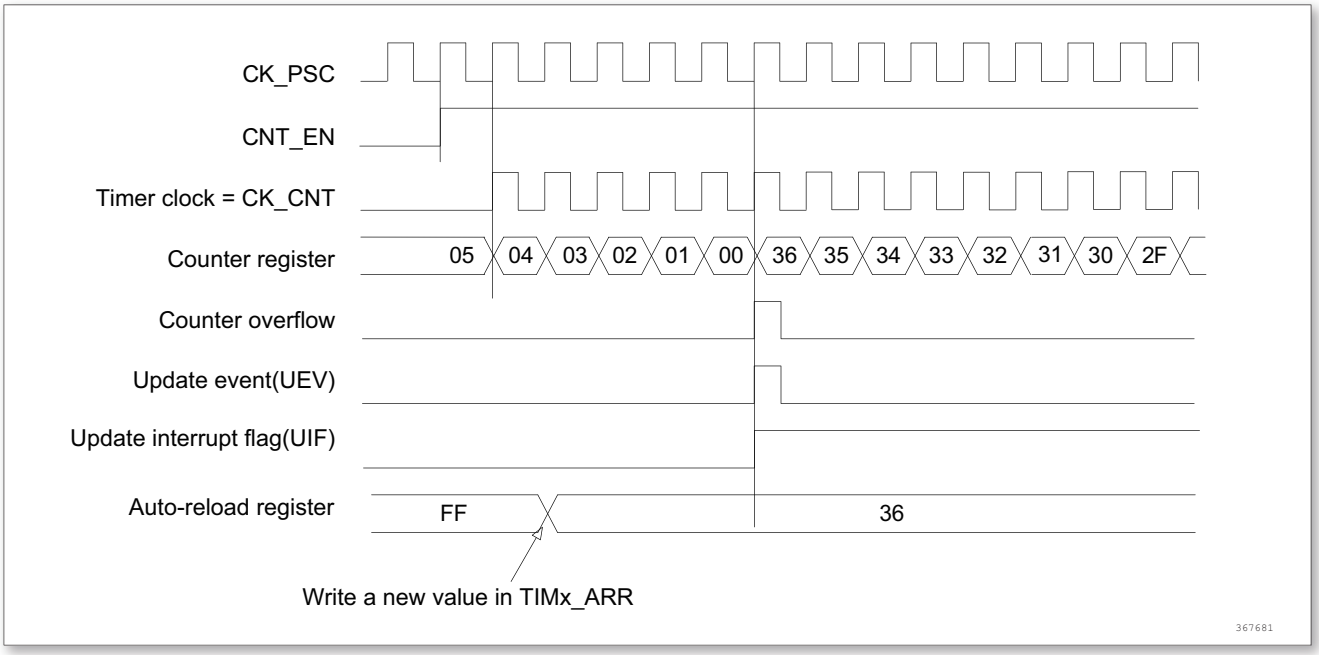

Figure 90. Counter Timing Diagram, Update Event when Repetition Counter is Not Used

Center-aligned mode (Upcounting/Downcounting))

In center-aligned mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register) －1, generates a counter overflow event, then counts from the auto-reload value down to 1 and generates a counter underflow event. Then it restarts counting from 0.

In this mode, the DIR direction bit in the TIMx_CR1 register cannot be written. It is updated by hardware and gives the current direction of the counter.

The update event can be generated at each counter overflow and at each counter underflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) . In this case, the counter restarts counting from 0, so does the counter of the prescaler.

The UEV update event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the

preload registers. Then, no update event occurs until UDIS bit has been written to 0. However, the counter continues counting up and down, based on the current auto-reload value.

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag bit(UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register).

Note: If the update source is a counter overflow, the auto-reload is updated before the counter is reloaded, so that the next period is the expected one (the counter is loaded with the new value).

The following figures show some examples of the counter behavior for different clock frequencies.

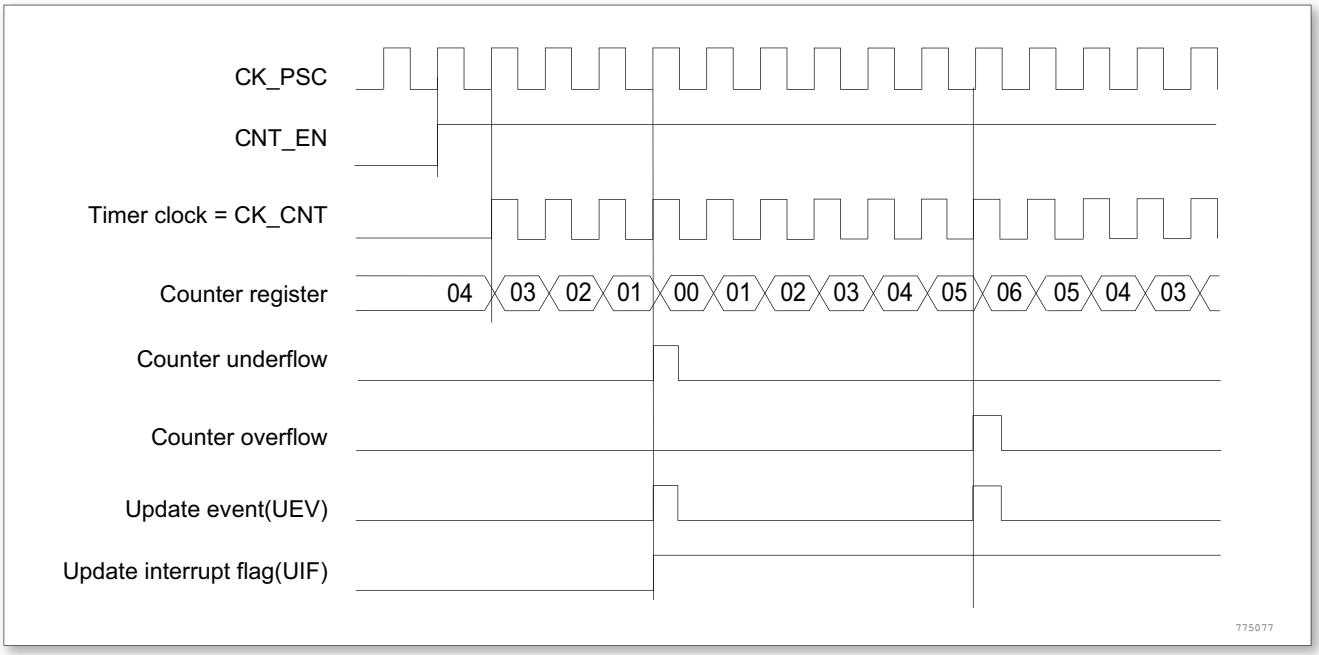

Figure 91. Counter Timing Diagram, Internal Clock Divided by 1, TIMx_ARR = 6

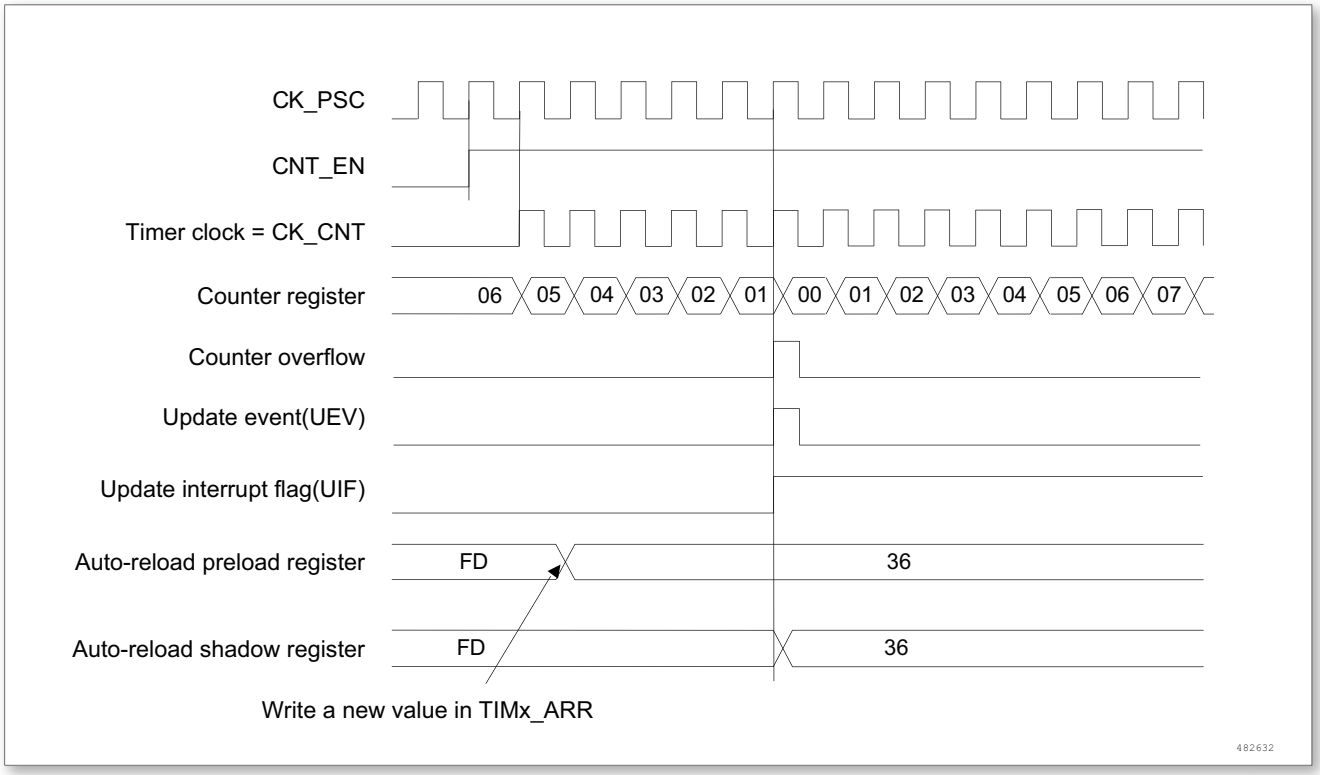

Figure 95. Counter Timing Diagram, Update Event with ARPE = 1(Counter Underflow)

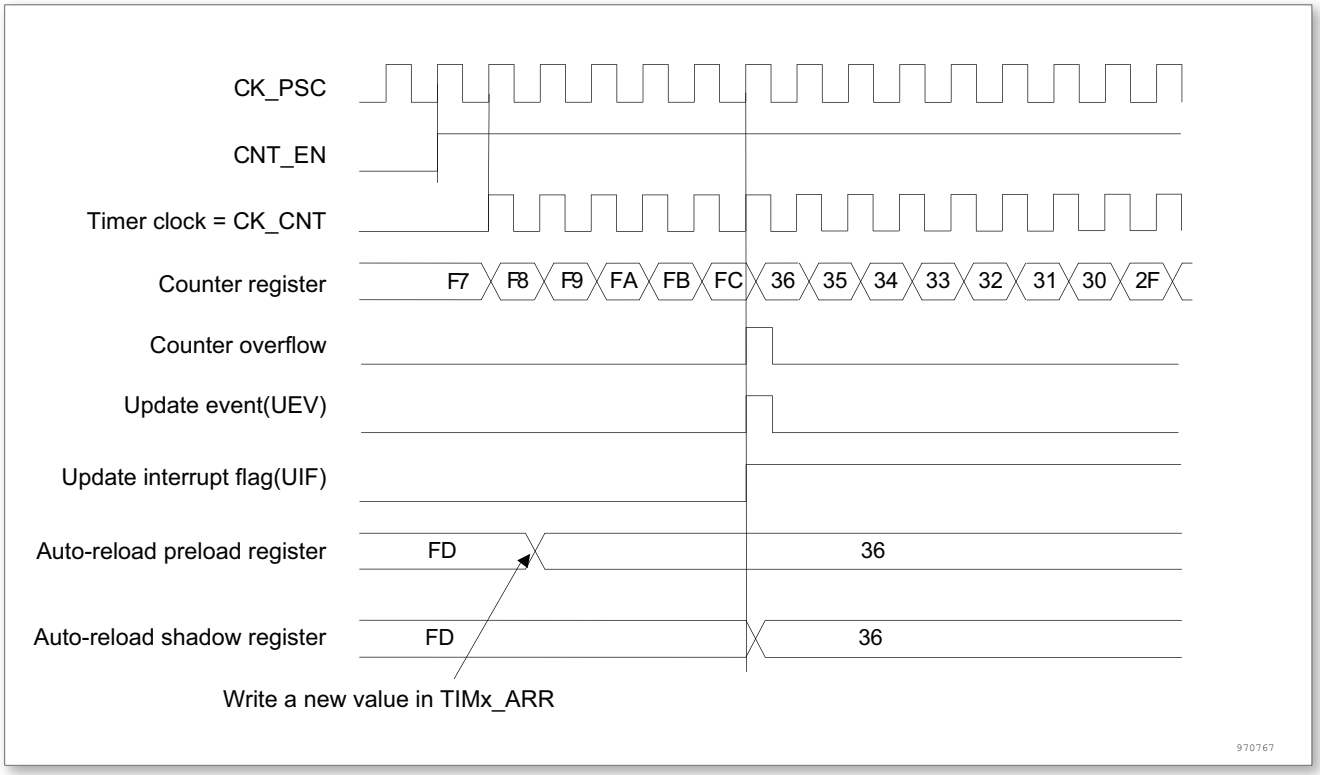

Figure 96. Counter Timing Diagram, Update Event with ARPE = 1(Counter Overflow))

12.3.3 Clock selection

The counter clock can be provided by the following clock sources:

- Internal clock (CK_INT).
- External clock mode1: external input pin (TIx).
- External clock mode2: external trigger input (ETR).
- Internal trigger inputs (ITRx): using one timer as prescaler for another timer, for example, the user can configure Timer 1 to act as a prescaler for Timer 2.

Internal clock (CK_INT)

If the slave mode controller is disabled (SMS=000), then the CEN, DIR (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock CK_INT.

The following figure shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

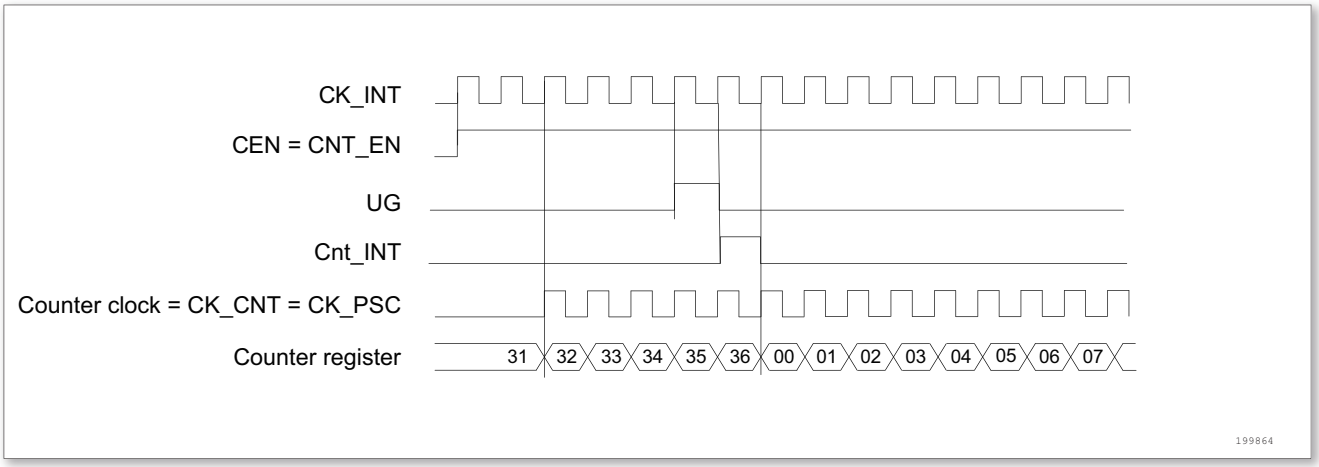

Figure 97. Control Circuit in Normal Mode, Internal Clock Divided By 1

External clock source mode 1

This mode is selected when SMS=111 in the TIMx_SMCR register. The counter can count at each rising or falling edge on a selected input.

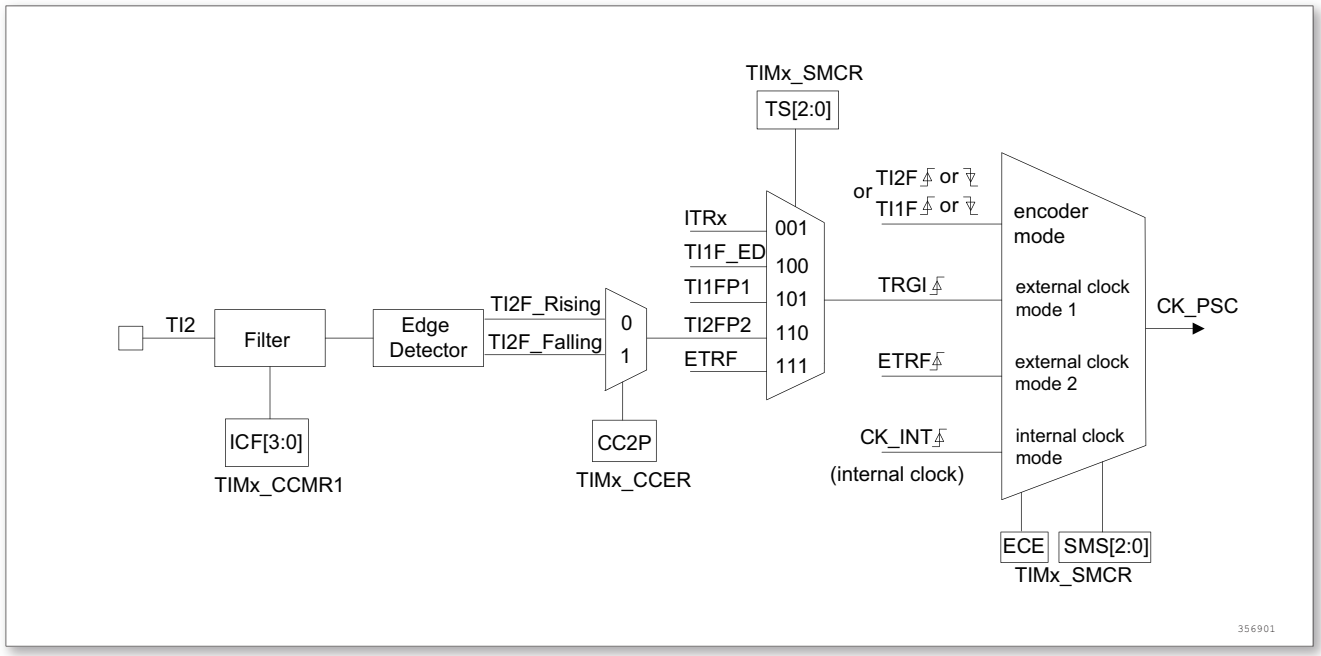

Figure 98. TI2 External Clock Connection Example

For example, to configure the upcounter to count in response to a rising edge on the TI2 input, use the following procedure:

1. Configure channel 2 to detect rising edges on the TI2 input by writing CC2S = ‘01’ in the TIMx_CCMR1 register.
2. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx_CCMR1 register (if no filter is needed, keep IC2F=0000). Note: The capture prescaler is not used for triggering, so there: Tno need to configure it.
3. Select rising edge polarity by writing CC2P=0 in the TIMx_CCER register.
4. Select the timer in external clock mode 1 by writing SMS=111 in the TIMx_SMCR register.

5. Select TI2 as the trigger input source by writing TS=110 in the TIMx_SMCR register.
6. Enable the counter by writing CEN=1 in the TIMx_CR1 register.

When a rising edge occurs on TI2, the counter counts once and the TIF flag is set.

The delay between the rising edge on TI2 and the actual clock of the counter is due to the resynchronization circuit on TI2 input.

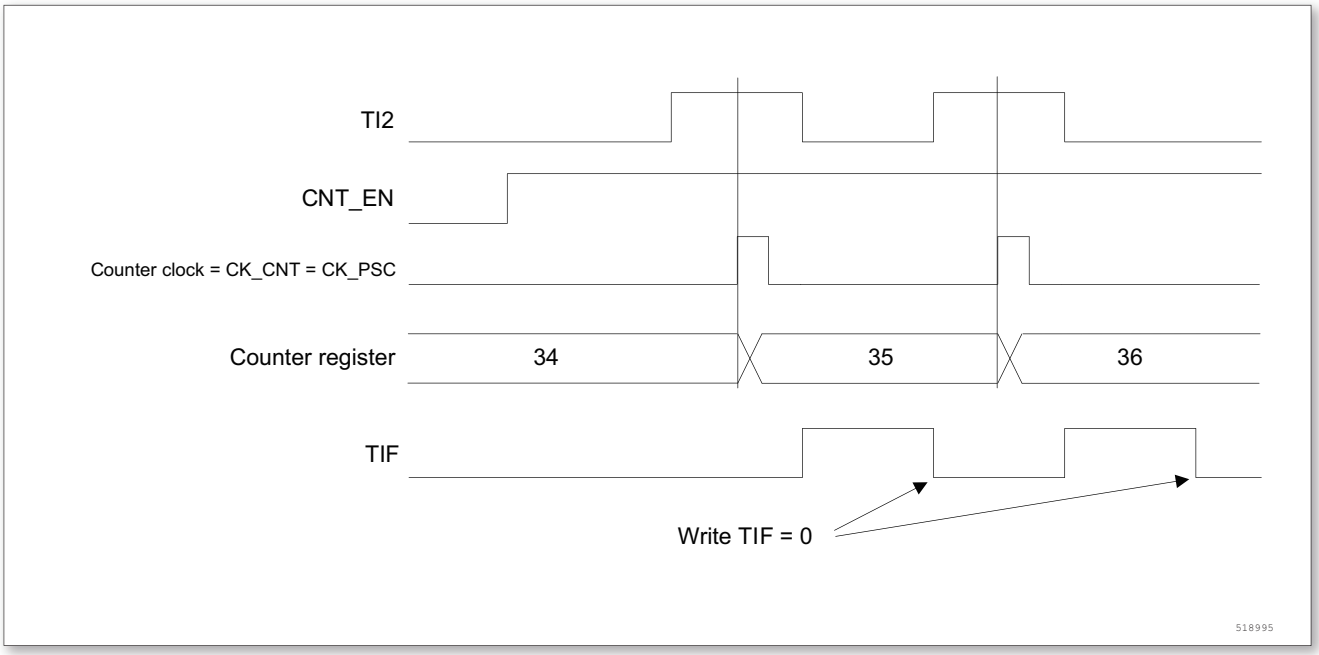

Figure 99. Control Circuit in External Clock Mode 1

External clock source mode 2

This mode is selected by writing ECE = 1 in the TIMx_SMCR register.

The counter can count at each rising or falling edge on the external trigger input ETR.

The following figure gives an overview of the external trigger input block.

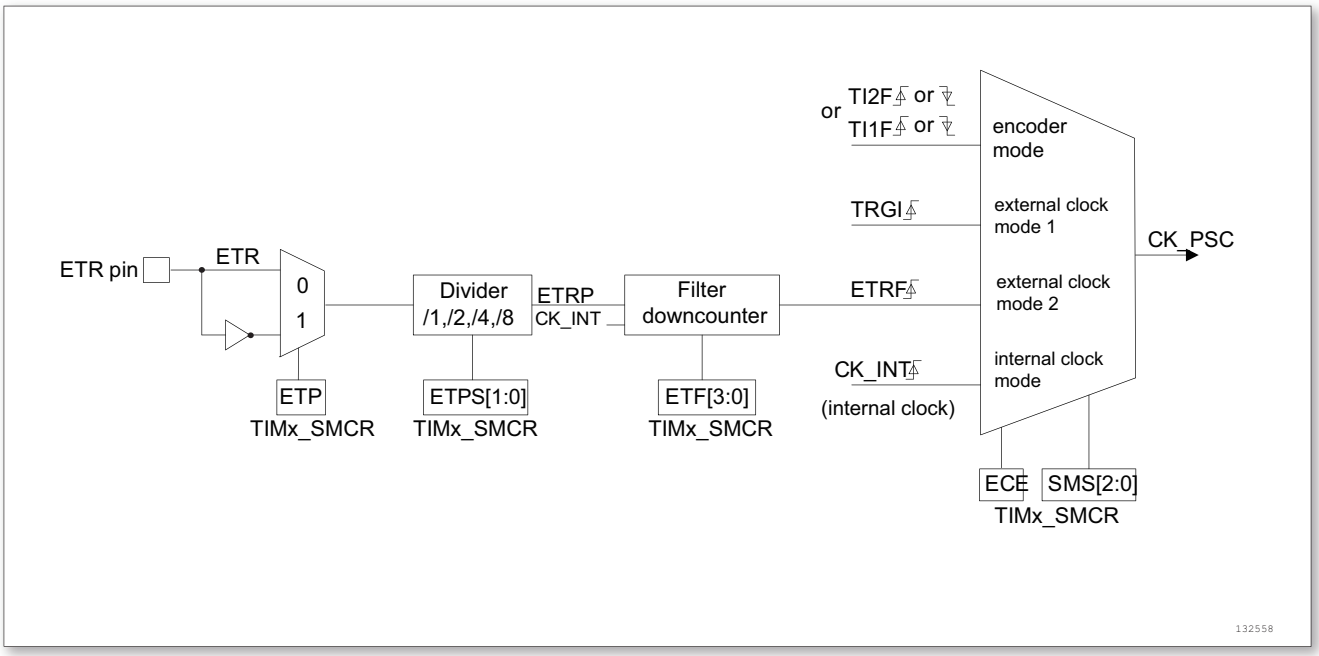

Figure 100. External Trigger Input Block

For example, to configure the upcounter to count once each 2 rising edges on ETR, use the following procedure:

- As no filter is needed in this example, write ETF [3:0]=0000 in the TIMx_SMCR register.
- Set the prescaler by writing ETPS [1:0]=01 in the TIMx_SMCR register.
- Select rising edge detection on the ETR pin by writing ETP=0 in the TIMx_SMCR register.
- Enable external clock mode 2 by writing ECE=1 in the TIMx_SMCR register.
- Enable the counter by writing CEN=1 in the TIMx_CR1 register.

The counter counts once each 2 ETR rising edges.

The delay between the rising edge on ETR and the actual clock of the counter is due to the resynchronization circuit on the ETRP signal.

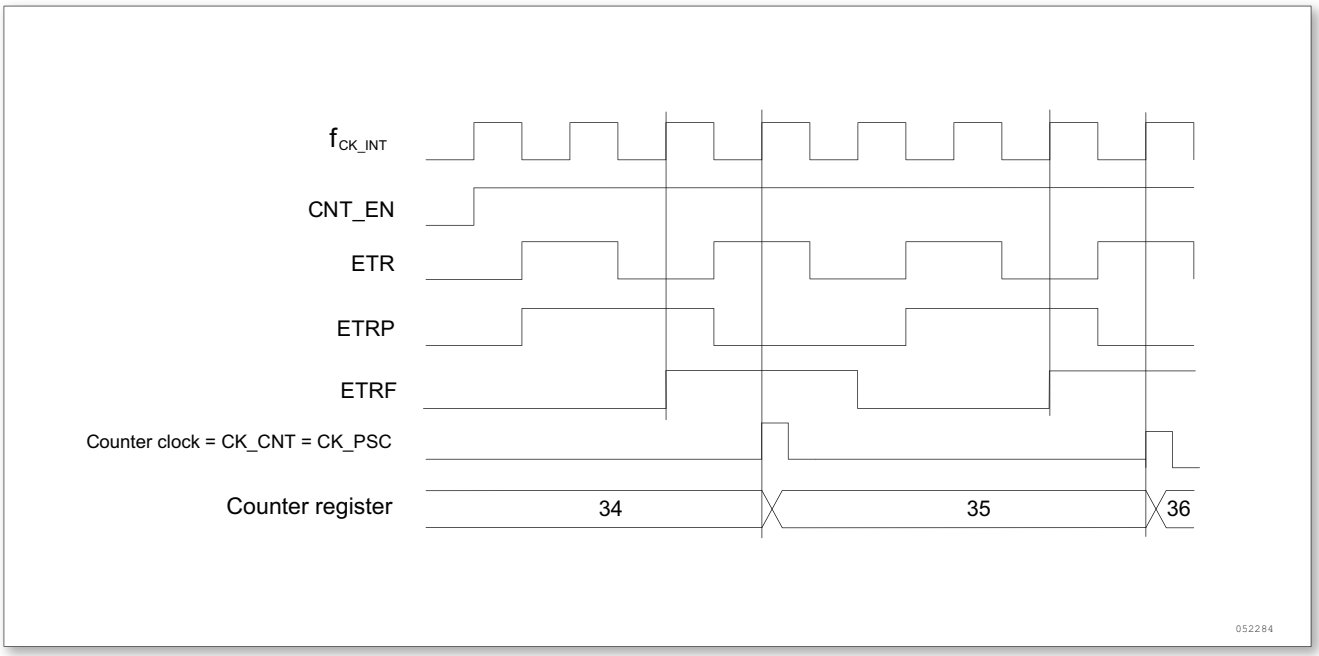

Figure 101. Control Circuit in External Clock Mode 2

12.3.4 Capture/compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), including an input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control).

The following figures show a capture/compare channel. The input stage samples the corresponding TIx input to generate a filtered signal TIxF. Then, an edge detector with polarity selection generates a signal (TIxFPx) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).

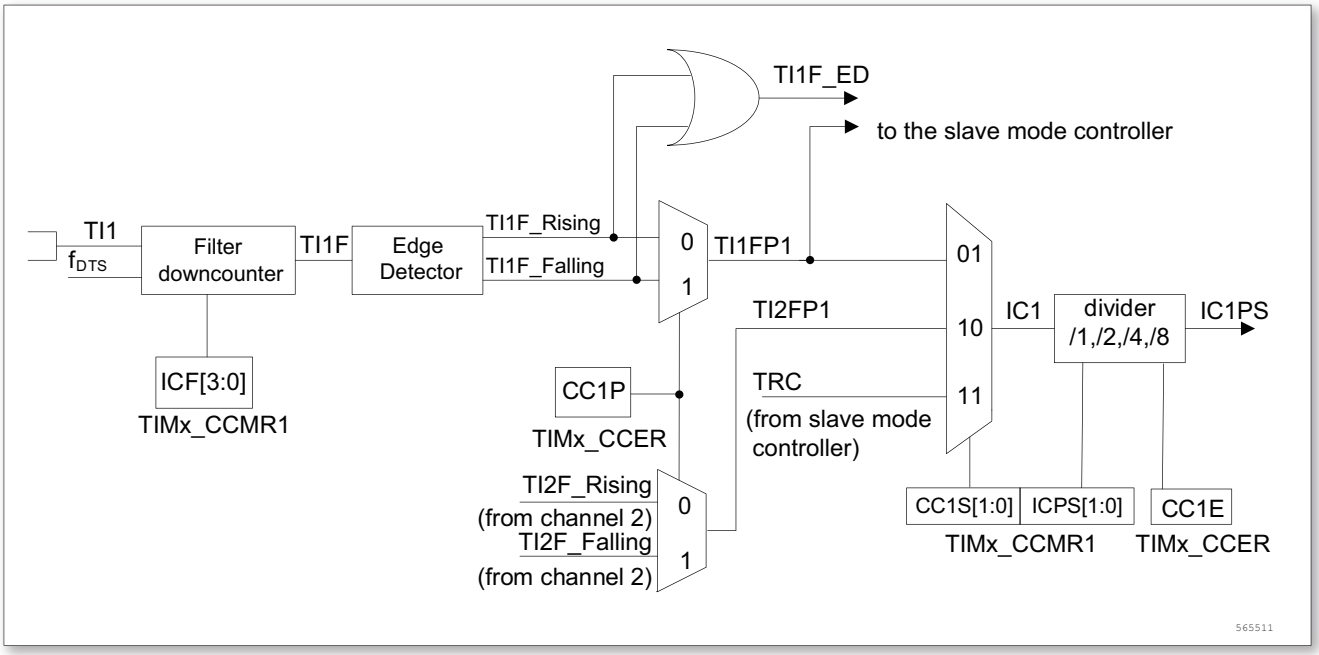

Figure 102. Capture/Compare Channel (Example: Channel 1 Input Stage)

The output stage generates an intermediate waveform which is then used for reference: OCxRef (active high). The polarity acts at the end of the chain.

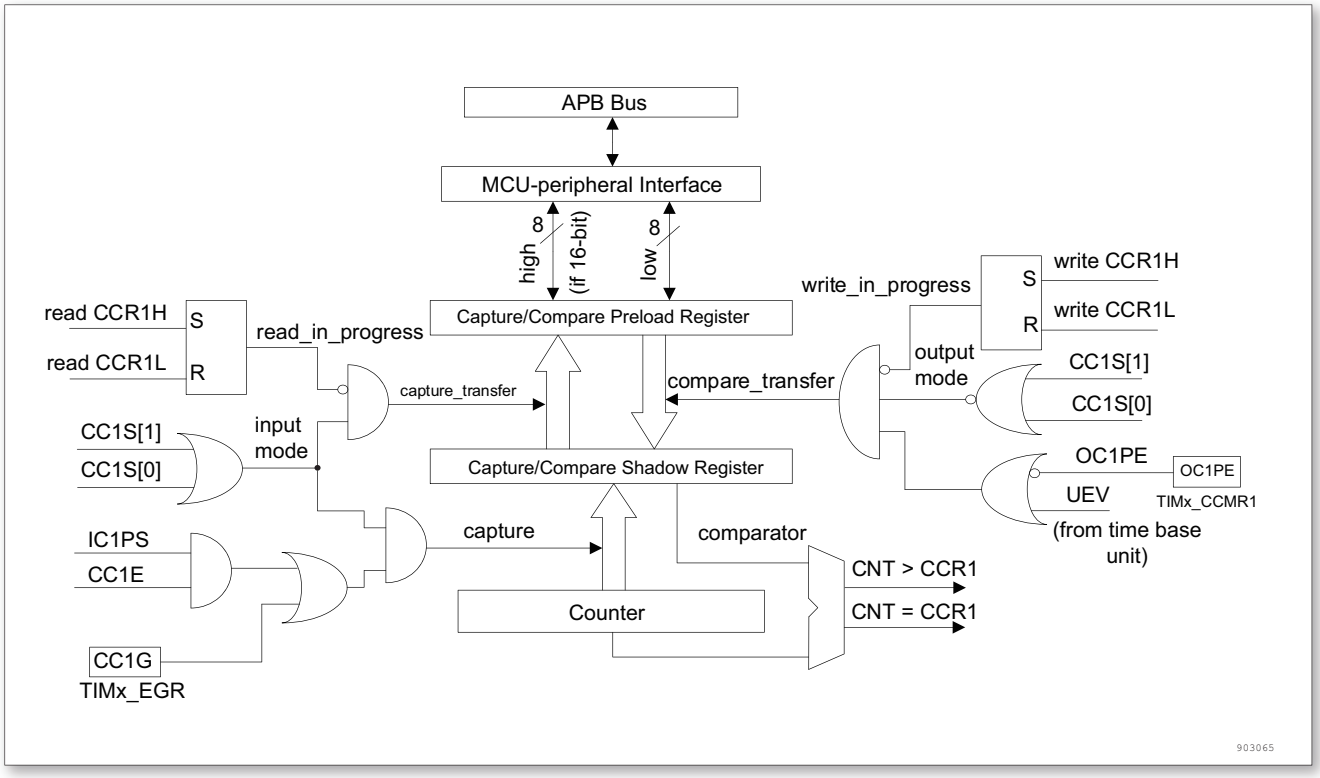

Figure 103. Capture/Compare Channel 1 Main Circuit

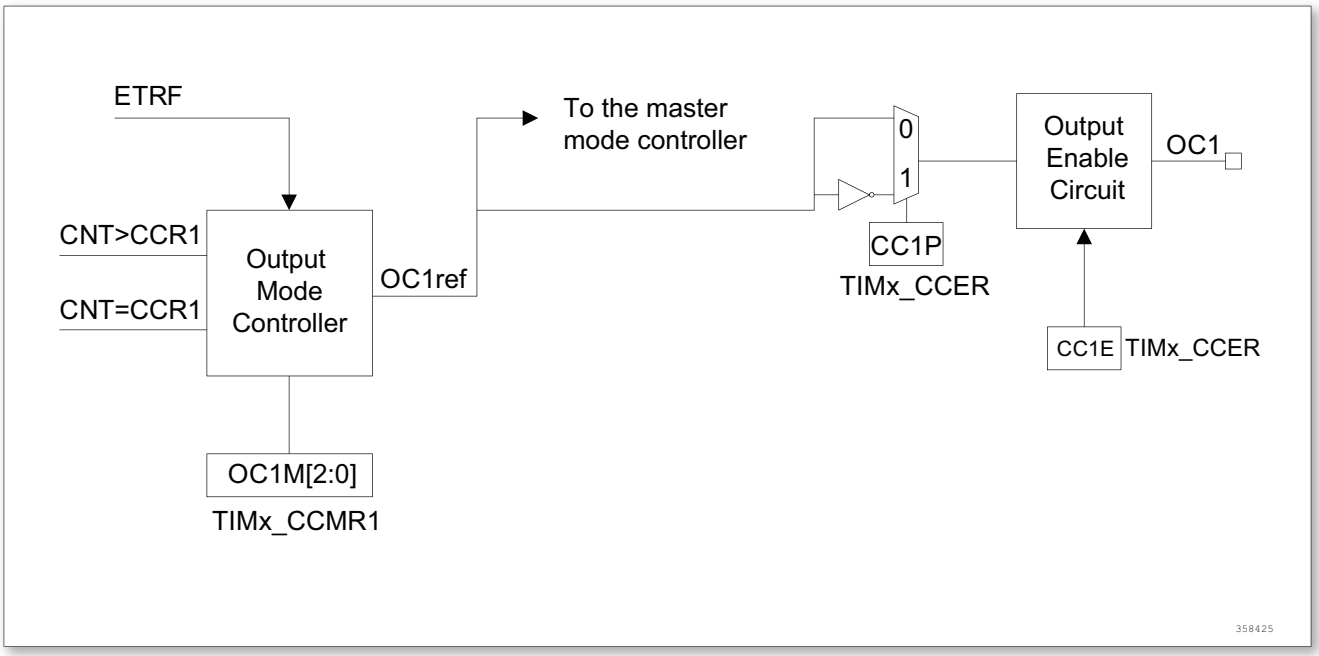

Figure 104. Output Stage of Capture/Compare Channel (Channel 1)

The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register. In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

12.3.5 Input capture mode

In Input capture mode, the Capture/Compare Registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCxIF flag (TIMx_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxOF (TIMx_SR register) is set. CCxIF can be cleared by software by writing it to '0' or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when written to '0'.

The following example shows how to capture the counter value in TIMx_CCR1 when TI1 input rises. To do this, use the following procedure:

- Select the active input: TIMx_CCR1 must be linked to the TI1 input, so write the CC1S bits to 01 in the TIMx_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIMx_CCR1 register becomes read-only.
- Program the needed input filter duration with respect to the signal connected to the timer (by programming ICxF bits in the TIMx_CCMRx register if the input is a TIx input). Let's imagine that, when toggling, the input signal is not stable during at most five internal clock cycles. We must program a filter duration longer than these five clock cycles. We can validate a transition on TI1 when 8 consecutive samples with the new level have been detected (sampled at fDTS frequency). Then write IC1F bits to 0011 in the TIMx_CCMR1 register.

- Select the edge of the active transition on the TI1 channel by writing CC1P bit to 0 in the TIMx_CCER register (rising edge in this case).
- Configure the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to '00' in the TIMx_CCMR1 register).
- Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx_CCER register to '1'.
- If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx_DIER register.

When an input capture occurs:

- TIMx_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- CC1OF is also set to 1.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which could happen after reading the flag and before reading the data.

Note: IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx_EGR register.

12.3.6 PWM input mode

This mode is a particular case of input capture mode. The procedure is the same except:

- Two ICx signals are mapped on the same TIx input.
- These 2 ICx signals are active on edges with opposite polarity.
- One of the two TIxFP signals is selected as trigger input and the slave mode controller is configured in reset mode.

For example, the user can measure the period (in TIMx_CCR1 register) and the duty cycle (in TIMx_CCR2 register) of the PWM applied on TI1 using the following procedure (depending on CK_INT frequency and prescaler value):

- Select the active input for TIMx_CCR1: write the CC1S bits to 01 in the TIMx_CCMR1 register (TI1 selected).
- Select the active polarity for TI1FP1 (used both for capture in TIMx_CCR1 and counter clear): write the CC1P bit to '0' (active on rising edge).
- Select the active input for TIMx_CCR2: write the CC2S bits to 10 in the TIMx_CCMR1 register (TI1 selected).
- Select the active polarity for TI1FP2 (used for capture in TIMx_CCR2): write the CC2P bit to '1' (active on falling edge).
- Select the valid trigger input: write the TS bits to 101 in the TIMx_SMCR register (TI1FP1 selected).
- Configure the slave mode controller in reset mode: write the SMS bits to 100 in the

TIMx_SMCR register.

- Enable the captures: write the CC1E and CC2E bits to ‘1’ in the TIMx_CCER register.

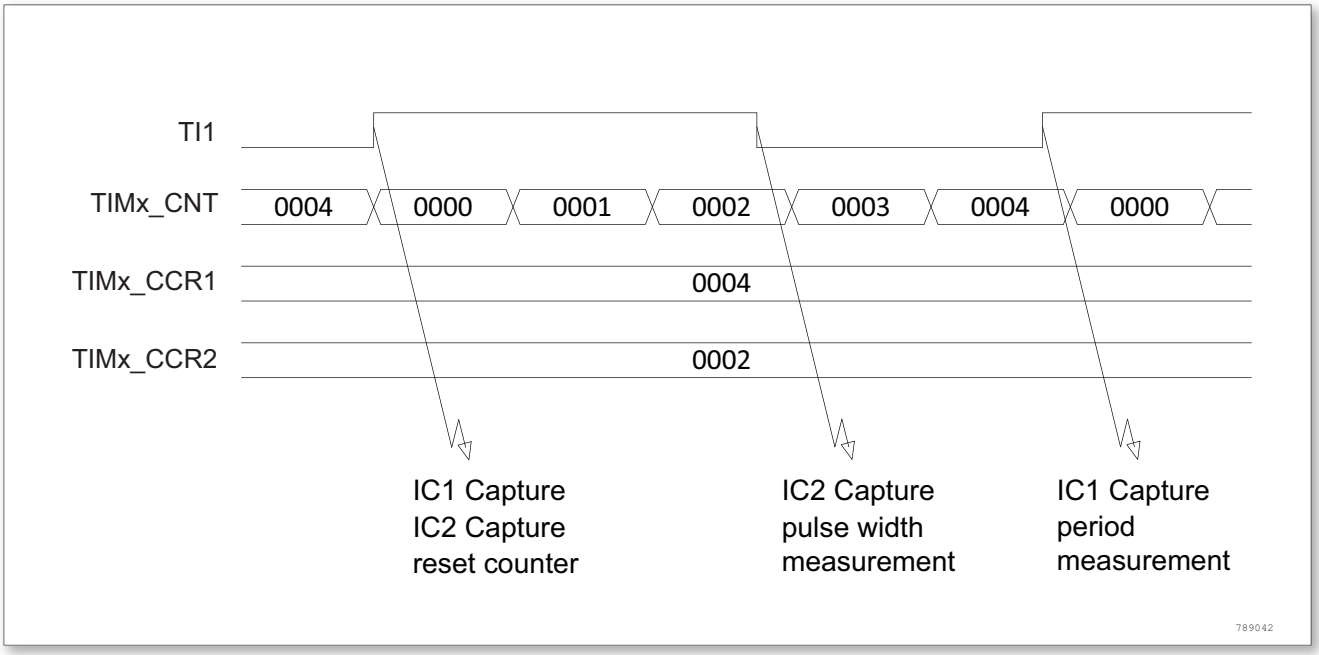

Figure 105. Output Stage of Capture/Compare Channel (Channel 1)

The PWM input mode can be used only with the TIMx_CH1/TIMx_CH2 signals due to the fact that only TI1FP1 and TI2FP2 are connected to the slave mode.

12.3.7 Forced output mode

In output mode (CCxS bits = 00 in the TIMx_CCMRx register), each output compare signal (OCxREF and then OCx/OCxN) can be forced to active or inactive level directly by software, being independent of any comparison between the output compare register and the counter.

To force an output compare signal (OCXREF/OCx) to its active level, the user just needs to write 101 in the OCxM bits in the corresponding TIMx_CCMRx register. Thus OCXREF is forced high (OCxREF is always active high) and OCx get opposite value to CCxP polarity bit.

For example: CCxP=0 (OCx active high) => OCx is forced to high level.

The OCxREF signal can be forced low by writing the OCxM bits to 100 in the TIMx_CCMRx register.

Anyway, in this mode, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the output compare mode section below.

12.3.8 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output

compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP bit in the TIMx_CCER register). The output pin can keep its level (OCXM=000), be set active (OCxM=001), be set inactive (OCxM=010) or can toggle (OCxM=011) on match.
- Sets a flag bit in the interrupt status register (CCxIF bit in the TIMx_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCXIE bit in the TIMx_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx_DIER register, CCDS bit in the TIMx_CR2 register for the DMA request selection).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

In output compare mode, the update event UEV has no effect on OCxREF and OCx output.

The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One Pulse mode)

Procedure:

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
3. Set the CCxIE and/or CCxDE bits if an interrupt and/or a DMA request is to be generated.
4. Select the output mode. For example, the user must write OCxM=011, OCxPE=0, CCxP=0 and CCxE=1 to toggle OCx output pin when CNT matches CCRx, CCRx preload is not used, OCx is enabled and active high.
5. Enable the counter by setting the CEN bit in the TIMx_CR1 register.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE=’0’, else TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in the following figure.

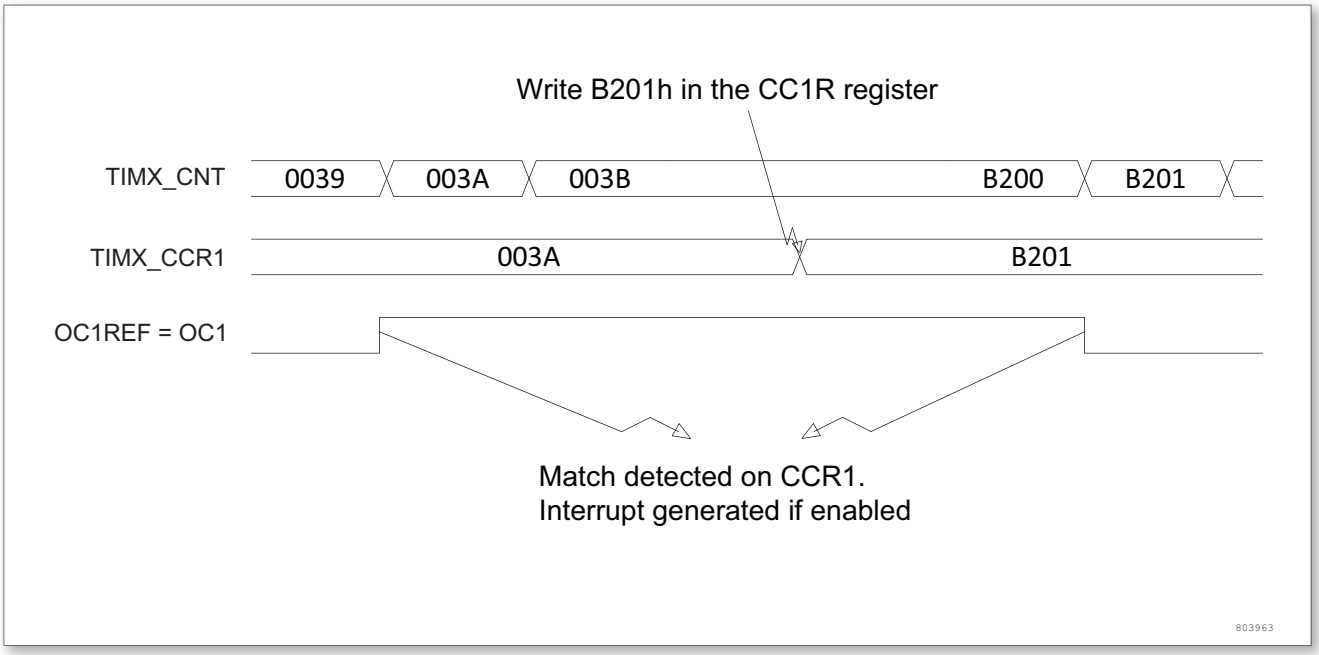

Figure 106. Output Compare Mode (Toggle OC1)

12.3.9 PWM mode

Pulse Width Modulation mode allows generating a signal with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per OCx output) by writing ‘110’ (PWM mode 1) or ‘111’ (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, the user must initialize all the registers by setting the UG bit in the TIMx_EGR register.

OCx polarity is software programmable using the CCxP bit in the TIMx_CCER register. It can be programmed as active high or active low. OCx output is enabled by the CCxE bit in the TIMx_CCER register. Refer to the TIMx_CCERx register description for more details.

In PWM mode (1 or 2), TIMx_CNT and TIM1_CCRx are always compared to determine whether TIM1_CCRx≤TIM1_CNT or TIM1_CNT≤TIM1_CCRx (depending on the direction of the counter). However, to comply with the OCREF_CLR (OCxREF can be cleared by an external event through the ETR signal until the next PWM period), the OCxREF signal is asserted only:

- When the result of the comparison changes
- When the output compare mode (OCxM bits in TIMx_CCMRx register) switches from the period), the OC enabled by the CCxE bit in the TIMx_CCER register. Refer to the

TIMx_CCERx register

This forces the PWM by software while the timer is running. The timer is able to generate PWM in edge-aligned mode or center-aligned mode depending on the CMS bits in the TIMx_CR1 register.

PWM edge-aligned mode

Upcounting configuration

Upcounting is active when the DIR bit in the TIMx_CR1 register is low.

In the following example, we consider PWM mode 1. The reference PWM signal OCxREF is high as long as TIMx_CNT < TIMx_CCRx, otherwise it becomes low. If the compare value in TIMx_CCRx is greater than the auto-reload value (in TIMx_ARR) then OCxREF is held at ‘1’. If the compare value is 0 then OCxRef is held at ‘0’. Figure 61 shows some edge-aligned PWM waveforms in an example where TIMx_ARR=8.

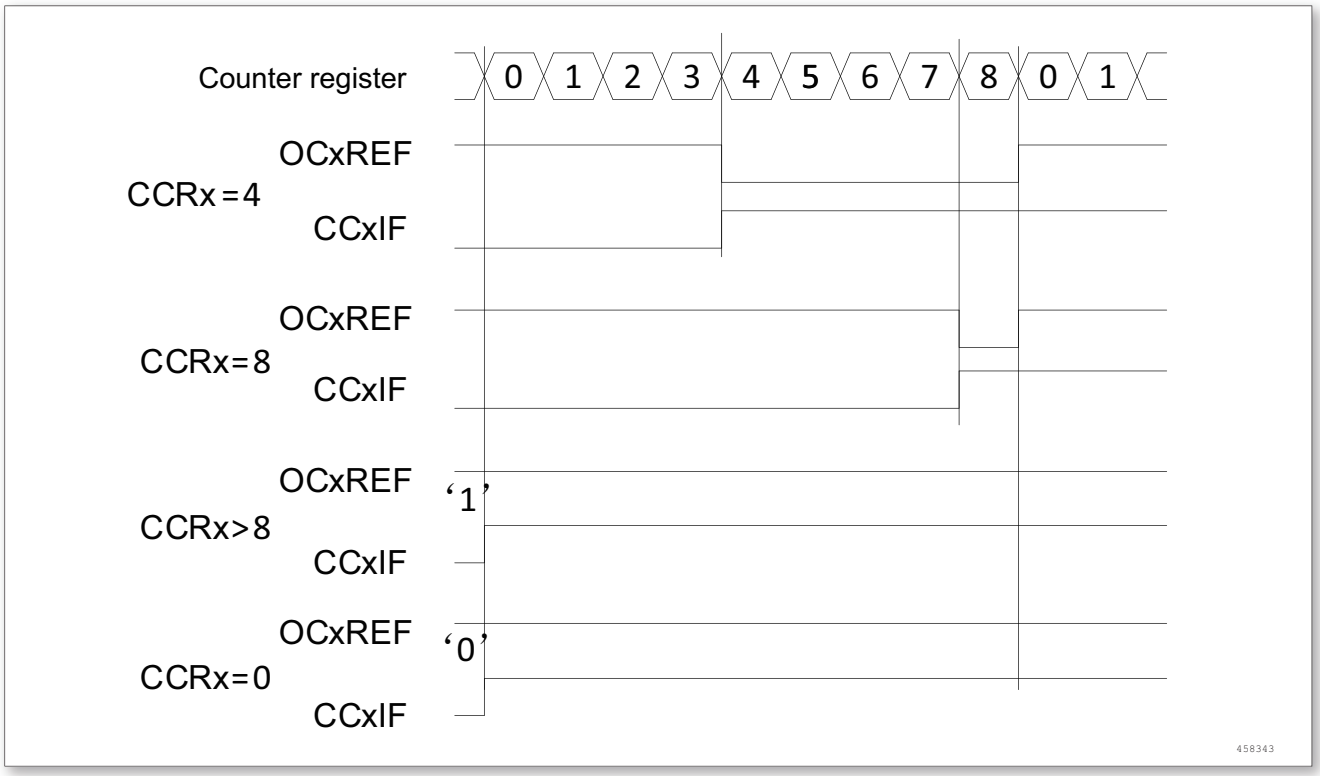

Figure 107. Edge-aligned PWM Waveforms (ARR = 8)

Downcounting configuration

Downcounting is active when DIR bit in TIMx_CR1 register is high.

In PWM mode 1, the reference signal OCxRef is low as long as TIMx_CNT > TIMx_CCRx, otherwise it becomes high. If the compare value in TIMx_CCRx is greater than the auto-reload value in TIMx_ARR, then OCxREF is held at ‘1’. 0% PWM is not possible in this mode.

PWM center-aligned mode

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are different from ‘00’ (all the remaining configurations having the same effect on the OCxRef/OCx signals).

The compare flag is set when the counter counts up, when it counts down or when it counts up and down depending on the CMS bits configuration. The direction bit (DIR) in the TIMx_CR1 register is updated by hardware and must not be changed by software. Refer to section 11.3.2 Center-aligned Mode.

The following figure shows some center-aligned PWM waveforms in an example, where:

- TIMx_ARR = 8
- PWM mode 1
- The flag is set when the counter counts down corresponding to the center-aligned mode 1 selected for CMS=01 in TIMx_CR1 register.

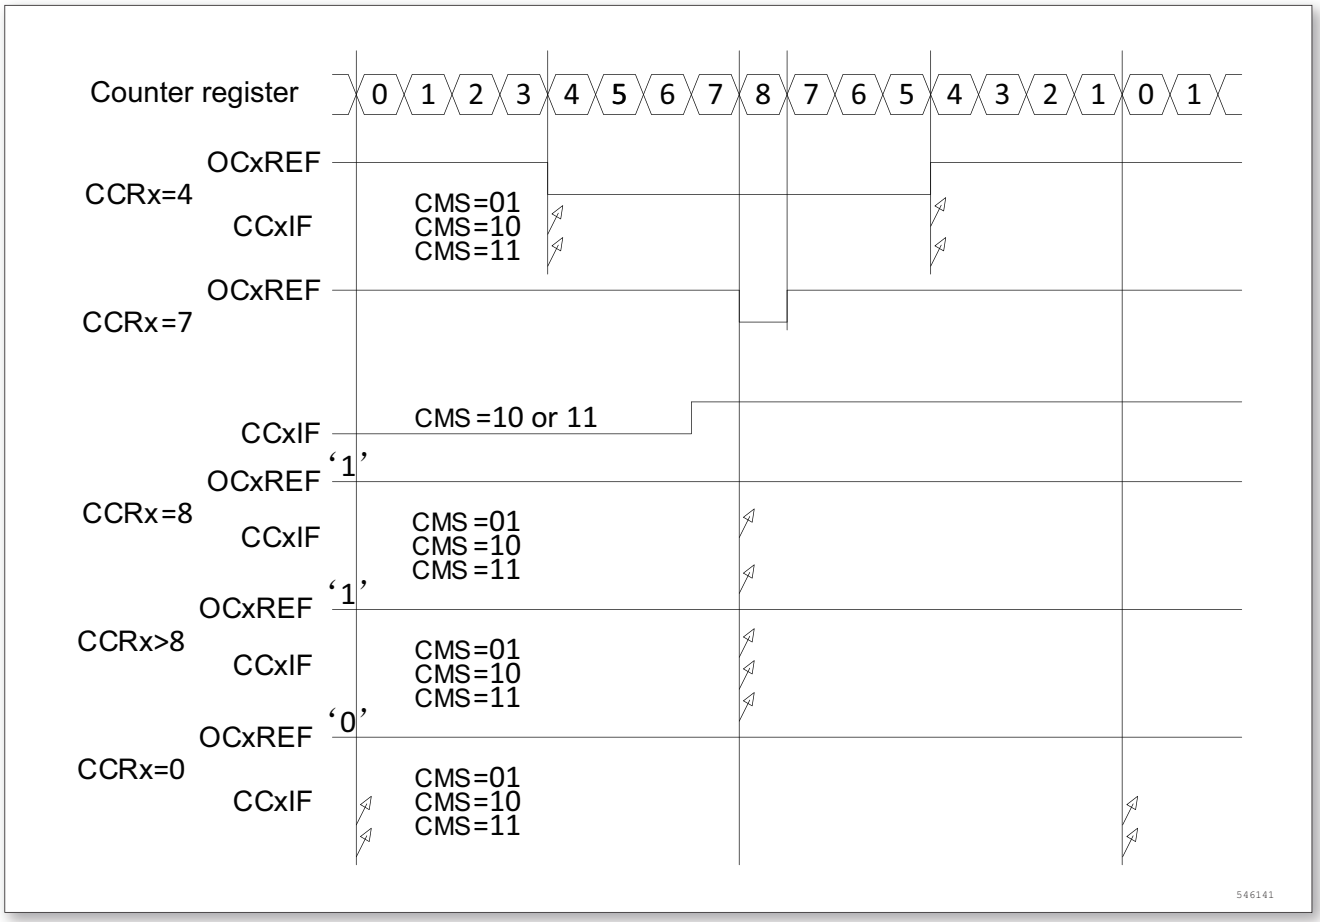

Figure 108. Center-aligned PWM Waveforms (ARR = 8)

Hints in center-aligned mode:

- When starting in center-aligned mode, the current up-down configuration is used. It means that the counter counts up or down depending on the value written in the DIR bit in the TIMx_CR1 register. Moreover, the DIR and CMS bits must not be changed at the same time by the software.
- Writing to the counter while running in center-aligned mode is not recommended as it can lead to unexpected results. In particular:
  - The direction is not updated if the user writes a value in the counter greater than the auto-reload value (TIMx_CNT>TIMx_ARR). For example, if the counter was counting up, it will continue to count up.

- The direction is updated if the user writes 0 or write the TIMx_ARR value in the counter but no Update Event UEV is generated

- The safest way to use center-aligned mode is to generate an update by software (setting the UG bit in the TIMx_EGR register) just before starting the counter and not to write the counter while it is running.

12.3.10 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. Select One-pulse mode by setting the OPM bit in the TIMx_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- In upcounting: CNT < CCRx ≤ ARR (in particular, 0 < CCRx)
- In downcounting: CNT > CCRx

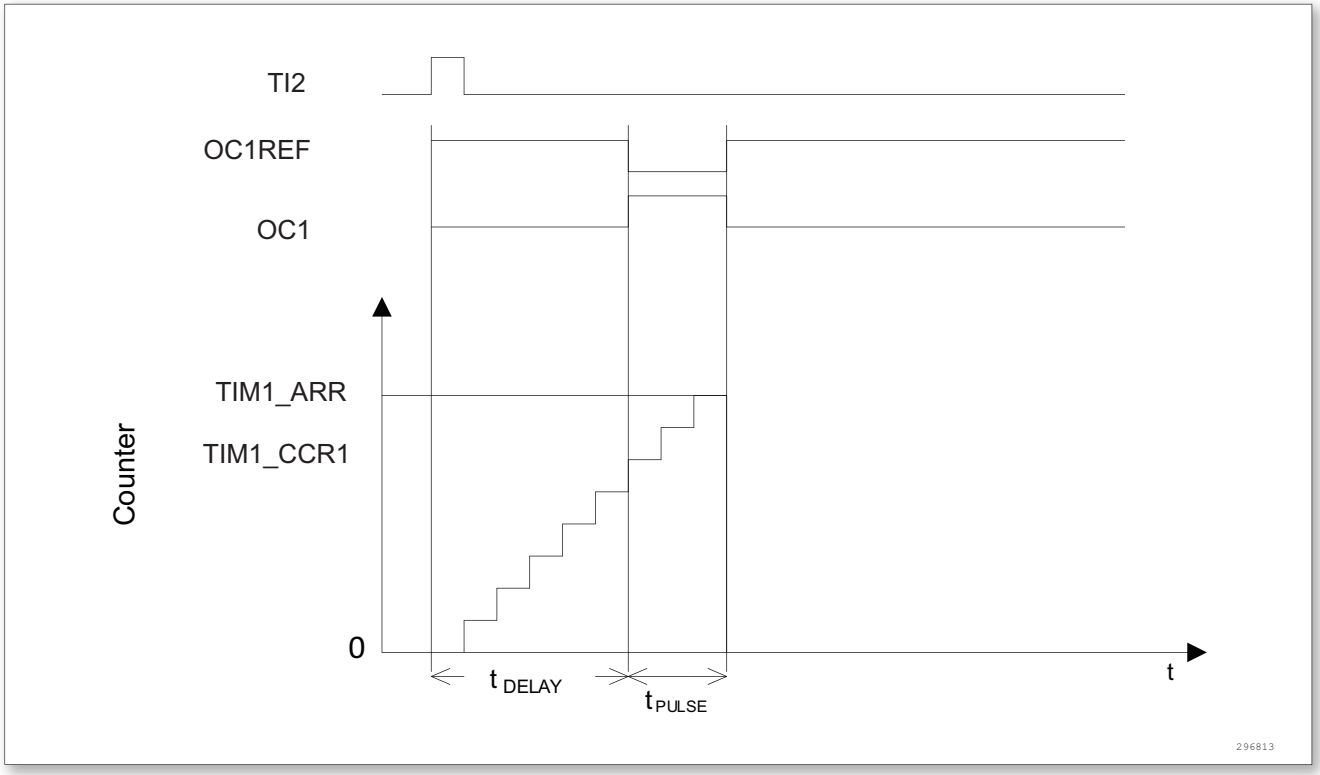

Figure 109. Example of One Pulse Mode

For example the user may want to generate a positive pulse on OC1 with a length of t_{PULSE} and after a delay of t_{DELAY} as soon as a positive edge is detected on the TI2 input pin.

Let’s use TI2FP2 as trigger 1:

- Map TI2FP2 to TI2 by writing CC2S = ’01’ in the TIMx_CCMR1 register.
- TI2FP2 must detect a rising edge, write CC2P = ’0’ in the TIMx_CCER register.
- Configure TI2FP2 as trigger for the slave mode controller (TRGI) by writing TS = ’110’ in the TIMx_SMCR register.
- TI2FP2 is used to start the counter by writing SMS to ’110’ in the TIMx_SMCR register (trigger mode).

The OPM waveform is defined by the value written in the compare registers (taking into account the clock frequency and the counter prescaler)

- The t_{DELAY} is defined by the value written in the TIMx_CCR1 register.
- The t_{PULSE} is defined by the difference between the auto-reload value and the compare value (TIMx_ARR - TIMx_CCR1).
- Let us say the user wants to build a waveform with a transition from ’0’ to ’1’ when a compare match occurs and a transition from ‘1’ to ‘0’ when the counter reaches the auto-reload value. To do this, enable PWM mode 2 by writing OC1M=111 in the TIMx_CCMR1 register. The user can optionally enable the preload registers by writing OC1PE=’1’ in the TIMx_CCMR1 register and ARPE in the TIMx_CR1 register. In this case the compare value must be written in the TIMx_CCR1 register, the auto-reload value in the TIMx_ARR register, generate an update by setting the UG bit and wait for external trigger event on TI2. CC1P is written to ‘0’ in this example.

In our example, the DIR and CMS bits in the TIMx_CR1 register should be low.

The user only wants one pulse (Single mode), so ’1’ must be written in the OPM bit in the TIMx_CR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0).

Particular case: OCx fast enable

In One-pulse mode, the edge detection on TIx input sets the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay t_{DELAY} min we can get.

If the user wants to output a waveform with the minimum delay, the OCxFE bit in the TIMx_CCMRx register must be set. Then OCxRef (and OCx) are forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

12.3.11 Clearing the OCxREF signal on an external event

The OCxREF signal for a given channel can be driven Low by applying a High level to the ETRF input (OCxCE enable bit of the corresponding TIMx_CCMRx register set to ‘1’). The OCxREF signal remains Low until the next update event, UEV, occurs.

This function can only be used in output compare and PWM modes, and does not work in forced mode.

For example, the OCxREF signal can be connected to the output of a comparator to be

used for current handling. In this case, the ETR must be configured as follow:

- The External Trigger Prescaler should be kept off: bits ETPS[1:0] of the TIMx_SMCR register set to ‘00’.
- The external clock mode 2 must be disabled: bit ECE of the TIMx_SMCR register set to ‘0’.
- The External Trigger Polarity (ETP) and the External Trigger Filter (ETF) can be configured according to the user needs.

The following Figure shows the behavior of the OCxREF signal when the ETRF Input becomes High, for both values of the enable bit OCxCE. In this example, the timer TIMx is programmed in PWM mode.

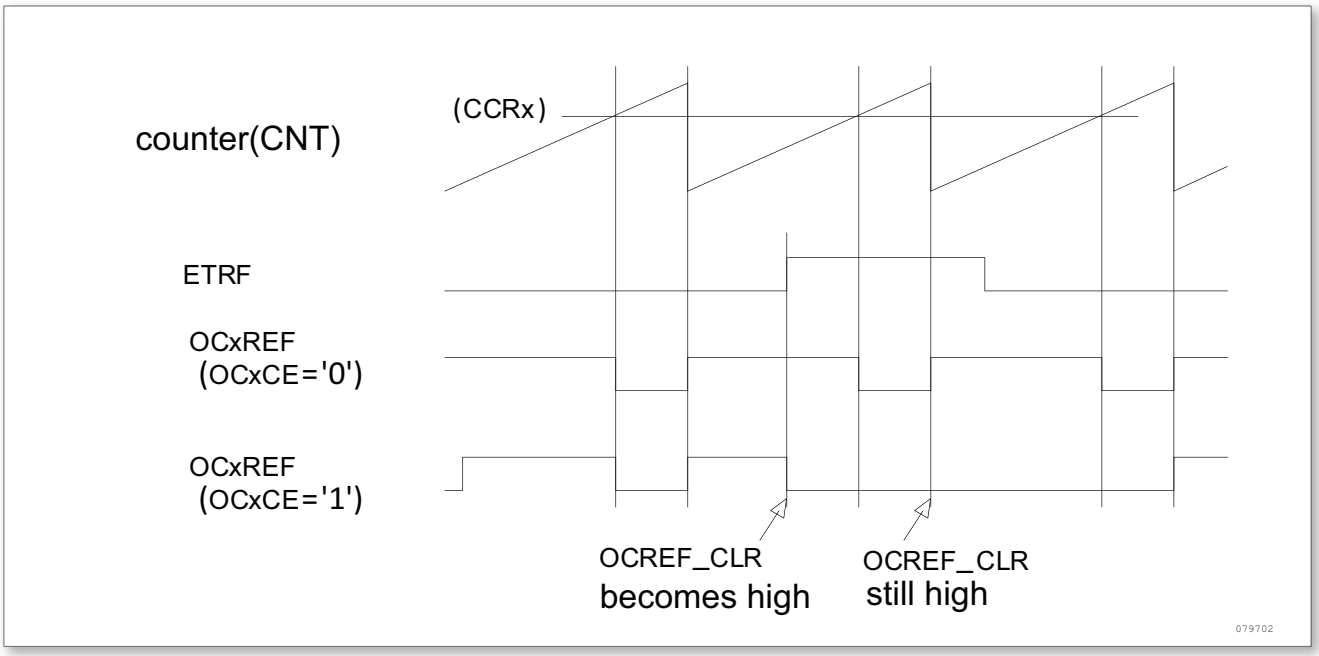

Figure 110. Clearing TIMx OCxREF

12.3.12 Encoder interface mode

To select Encoder Interface mode write SMS=‘001’ in the TIMx_SMCR register if the counter is counting on TI2 edges only, SMS=’010’ if it is counting on TI1 edges only and SMS=’011’ if it is counting on both TI1 and TI2 edges.

Select the TI1 and TI2 polarity by programming the CC1P and CC2P bits in the TIMx_CCER register. When needed, the user can program the input filter as well.

The two inputs TI1 and TI2 are used to interface to an incremental encoder. Assuming that the counter is enabled (CEN bit in TIMx_CR1 register written to ‘1) in the following table, it is clocked by each valid transition on TI1FP1 or TI2FP2 (TI1 and TI2 after input filter and polarity selection, TI1FP1=TI1 if not filtered and not inverted, TI2FP2=TI2 if not filtered and not inverted). The sequence of transitions of the two inputs is evaluated and generates count pulses as well as the direction signal. Depending on the sequence the counter counts up or down, the DIR bit in the TIMx_CR1 register is modified by hardware accordingly. The DIR bit is calculated at each transition on any input (TI1 or TI2), whatever the counter is counting on TI1 only, TI2 only or both TI1 and TI2.

Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the auto-reload value in the TIMx_ARR register (0 to ARR or ARR down to 0 depending on the direction). So user must configure TIMx_ARR before starting. In the same way, the capture, compare, prescaler, trigger output features continue to work as normal.

In this mode, the counter is modified automatically following the speed and the direction of the incremental encoder and its content, therefore, always represents the encoder’s position. The count direction corresponds to the rotation direction of the connected sensor. The following table summarizes the possible combinations, assuming TI1 and TI2 do not switch at the same time.

Table 41. Counting Direction Versus Encoder Signals

Active edge	Level on opposite signal (TI1FP1 for TI2, TI2FP2 for TI1)	TI1FP1 signal		TI1FP2 signal	
		Rising	Falling	Rising	Falling
Counting on TI1 only	High	Down	Up	No Count	No Count
	Low	Up	Down	No Count	No Count
Counting on TI2 only	High	No Count	No Count	Up	Down
	Low	No Count	No Count	Down	Up
Counting on TI1 and TI2	High	Down	Up	Up	Down
	Low	Up	Down	Down	Up

An external incremental encoder can be connected directly to the MCU without external interface logic. However, comparators are normally be used to convert the encoder’s differential outputs to digital signals. This greatly increases noise immunity. The third encoder output which indicate the mechanical zero position, may be connected to an external interrupt input and trigger a counter reset.

The following figure gives an example of counter operation, showing count signal generation and direction control. It also shows how input jitter is compensated where both edges are selected. This might occur if the sensor is positioned near to one of the switching points.

For this example, we assume that the configuration is the following:

- CC1S=’01’ (TIMx_CCMR1 register, TI1FP1 mapped on TI1).
- CC2S=’01’ (TIMx_CCMR2 register, TI1FP2 mapped on TI2).
- CC1P=’0’, (TIMx_CCER register, IC1FP1 non-inverted, IC1FP1=TI1).
- C2P= ’0’ (TIMx_CCER register, IC2FP2 non-inverted, IC2FP2=TI2).
- SMS= ’011’ (TIMx_SMCR register, all inputs are active on both rising and falling edges).
- CEN= ’1’ (TIMx_CR1 register, Counter enabled).

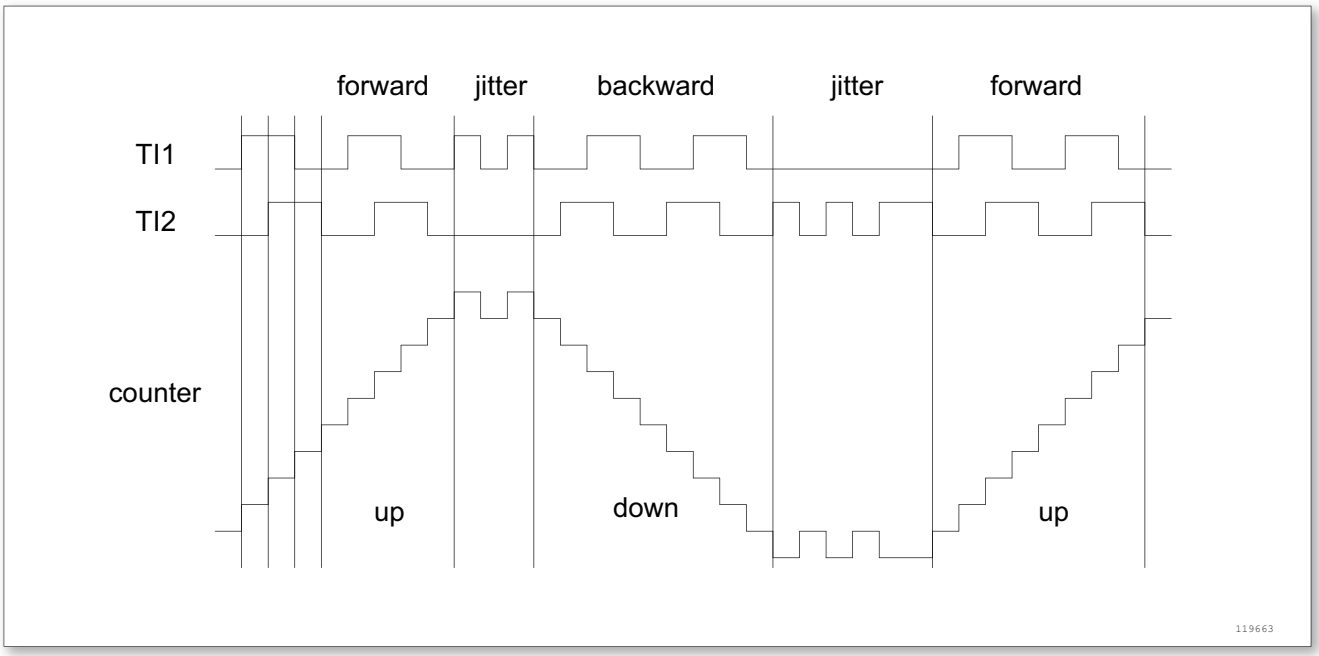

Figure 111. Example of Counter Operation in Encoder Mode

The following figure gives an example of counter behavior when IC1FP1 polarity is inverted (same configuration as above except CC1P=1).

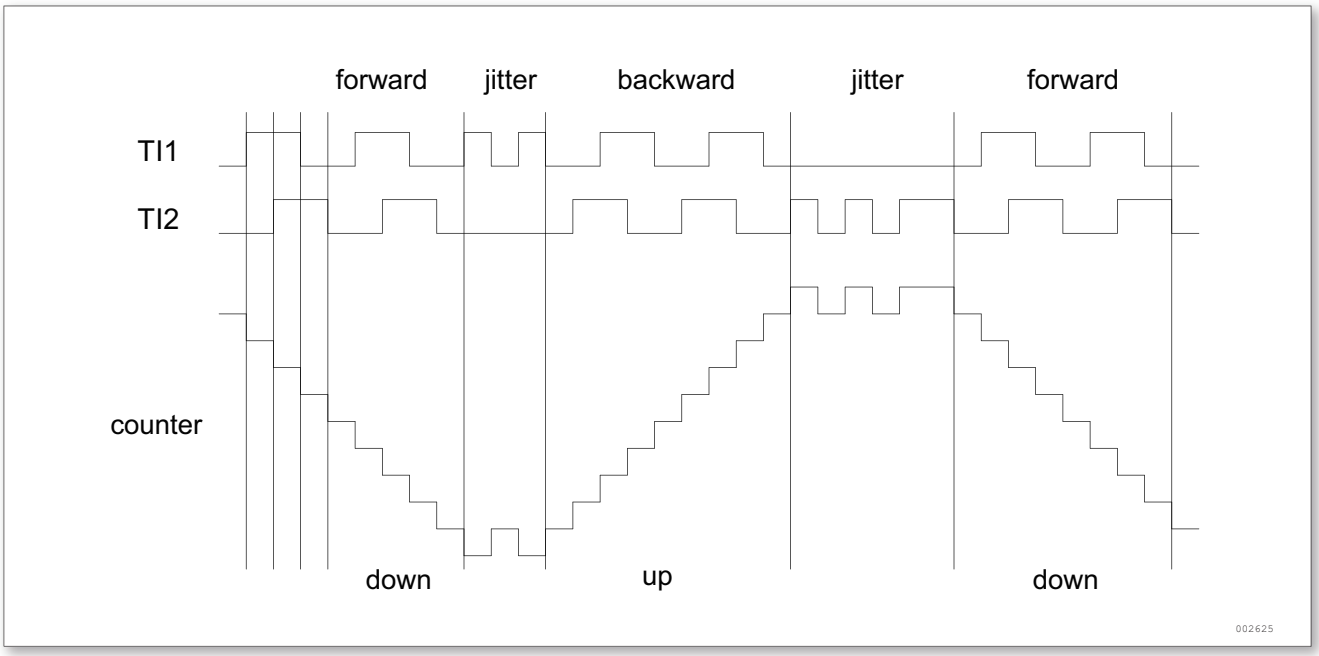

Figure 112. Example of Encoder Interface Mode with Inverted Polarity IC1FP1

The timer, when configured in Encoder Interface mode provides information on the sensor’ s current position.The user can obtain dynamic information (speed, acceleration, deceleration) by measuring the period between two encoder events using a second timer configured in capture mode. The output of the encoder which indicates the mechanical zero can be used for this purpose. Depending on the time between two events, the counter can also be read at regular times. This can be done by latching the counter value into a third input capture register if available (then the capture signal must be periodic and can be

generated by another timer). When available, it is also possible to read its value through a DMA request generated by a real-time clock.

12.3.13 Timer input XOR function

The TI1S bit in the TIMx_CR2 register, allows the input filter of channel 1 to be connected to the output of a XOR gate, combining the three input pins TIMx_CH1, TIMx_CH2 and TIMx_CH3.

The XOR output can be used with all the timer input functions such as trigger or input capture. An example of this feature used to interface Hall sensors is given in section 11.3.18.

12.3.14 Timers and external trigger synchronization

The TIMx timer can be synchronized with an external trigger in several modes: Reset mode, Gated mode and Trigger mode.

Slave mode: Reset mode

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx_CR1 register is low, an update event UEV is generated. Then, all the preloaded registers (TIMx_ARR, TIMx_CCRx) are updated.

- In the following example, the upcounter is cleared in response to a rising edge on TI1 input:
- Configure the channel 1 to detect rising edges on TI1. Configure the input filter duration (in this example, we don’t need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so the user does not need to configure it. The CC1S bits select the input capture source only, i.e. CC1S = 01 in the TIMx_CCMR1 register. Write CC1P=0 in TIMx_CCER register to validate the polarity (and detect rising edges only).
- Configure the timer in reset mode by writing SMS=100 in TIMx_SMCR register. Select TI1 as the input source by writing TS=101 in TIMx_SMCR register.
- Start the counter by writing CEN=1 in the TIMx_CR1 register.

The counter starts counting on the internal clock, then behaves normally until TI1 rising edge. When TI1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIMx_SR register) and an interrupt request, or a DMA request can be sent if enabled depending on the TIE (interrupt enable) and TDE (DMA enable) bits in TIMx_DIER register.

The following figure shows this behavior when the auto-reload register TIMx_ARR=0x36. The delay between the rising edge on TI1 and the actual reset of the counter is due to the resynchronization circuit on TI1 input.

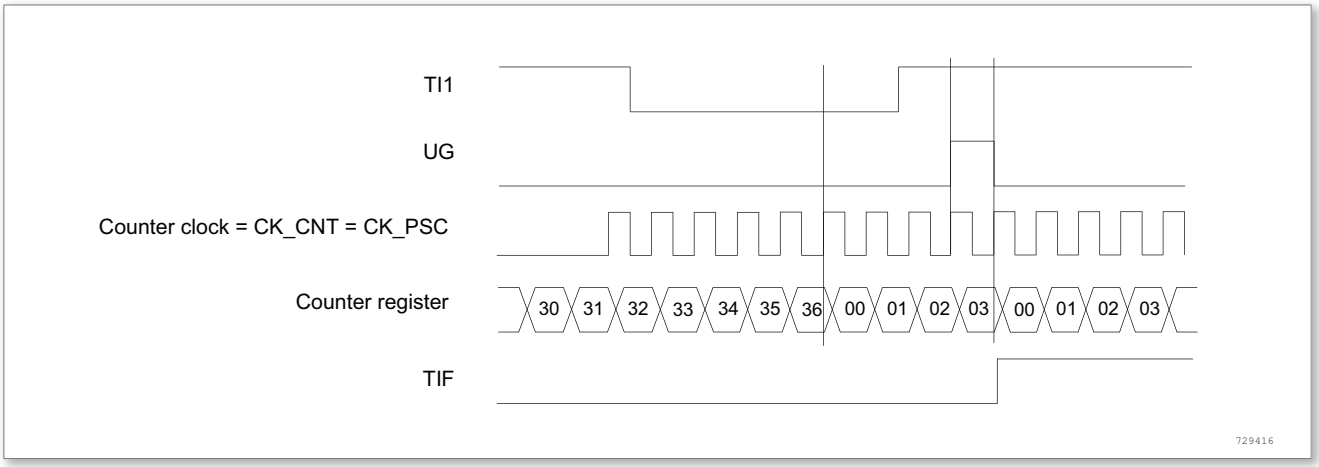

Figure 113. Control Circuit in Reset Mode

Slave mode: Gated mode

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when TI1 input is low:

- Configure the channel 1 to detect low level on TI1. Configure the input filter duration (in this example, we don't need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so the user does not need to configure it. The CC1S bits select the input capture source only, CC1S = 01 in the TIMx_CCMR1 register. Write CC1P=1 in TIMx_CCER register to validate the polarity (and detect low level only).
- Configure the timer in gated mode by writing SMS=101 in TIMx_SMCR register. Select TI1 as the input source by writing TS=101 in TIMx_SMCR register.
- Start the counter by writing CEN=1 in the TIMx_CR1 register. In gated mode, the counter doesn't start if CEN=0, whatever is the trigger input level

The counter starts counting on the internal clock as long as TI1 is low and stops as soon as TI1 becomes high. The TIF flag in the TIMx_SR register is set both when the counter starts or stops.

The delay between the rising edge on TI1 and the actual stop of the counter is due to the resynchronization circuit on TI1 input.

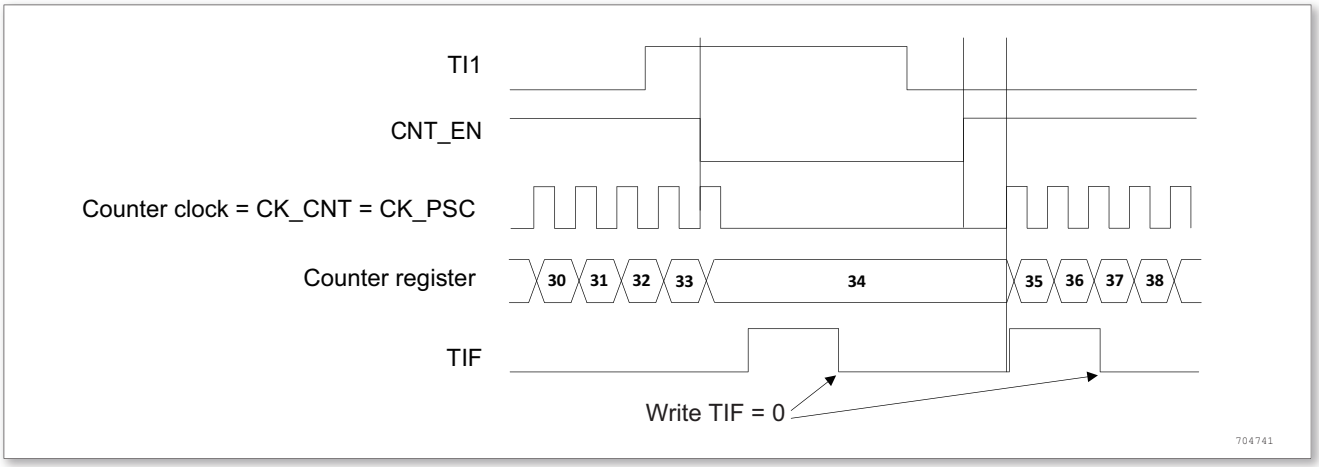

Figure 114. Control Circuit in Gated Mode

Slave mode: Trigger mode

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on TI2 input:

- Configure the channel 2 to detect rising edges on TI2. Configure the input filter duration (in this example, we don't need any filter, so we keep IC2F=0000). The capture prescaler is not used for triggering, so there's no need to configure it. The CC2S bits are only configured to select CC2P=1 in TIMx_CCER register, so as to validate the polarity (and detect low level only).
- Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select TI2 as the input source by writing TS=110 in TIMx_SMCR register.

When a rising edge occurs on TI2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on TI2 and the actual stop of the counter is due to the resynchronization circuit on TI2 input.

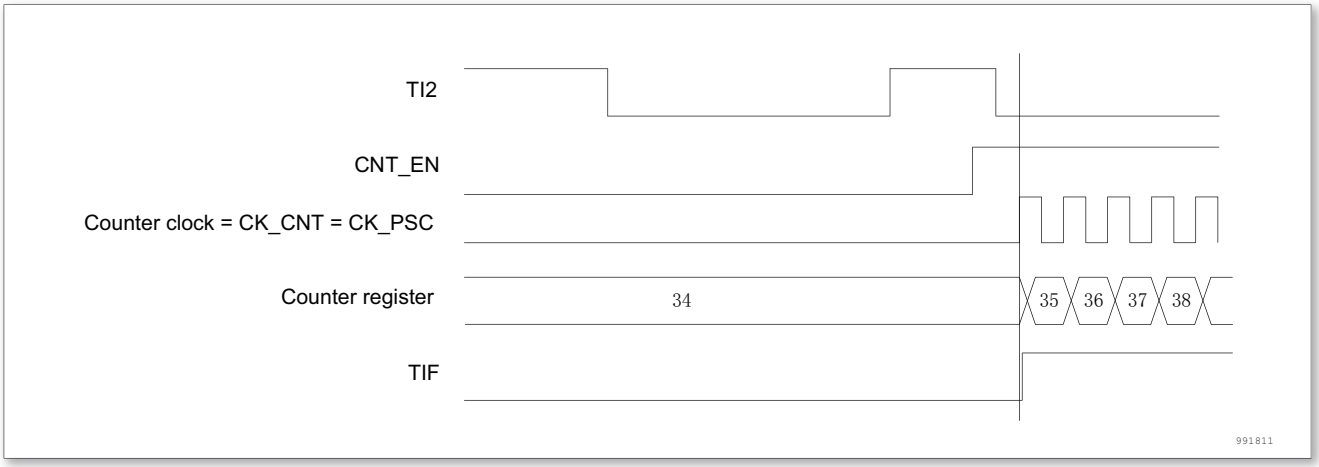

Figure 115. Control Circuit in Trigger Mode

Slave mode: External clock mode 2 + trigger mode

The external clock mode 2 can be used in addition to another slave mode (except external clock mode 1 and encoder mode). In this case, the ETR signal is used as external clock input, and another input can be selected as trigger input (in reset mode, gated mode or trigger mode). It is recommended not to select ETR as TRGI through the TS bits of TIMx_SMCR register.

In the following example, the upcounter is incremented at each rising edge of the ETR signal as soon as a rising edge of TI1 occurs:

- Configure the external trigger input circuit by programming the TIMx_SMCR register as follows:
  - ETF = 0000: no filter
  - ETPS = 00: prescaler disabled
  - ETP = 0: detection of rising edges on ETR and ECE=1 to enable the external clock mode 2.

- Configure the channel 1 as follows, to detect rising edges on T1:
  - IC1F=0000: no filter.
  - The capture prescaler is not used for triggering and does not need to be configured.
  - CC1S=01 in TIMx_CCMR1 register to select only the input capture source.
  - CC1P=0 in TIMx_CCER register to validate the polarity (and detect rising edge only).
- Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select TI1 as the input source by writing TS=101 in TIMx_SMCR register

A rising edge on TI1 enables the counter and sets the TIF flag. The counter then counts on ETR rising edges.

The delay between the rising edge of the ETR signal and the actual reset of the counter is due to the resynchronization circuit on ETRP input.

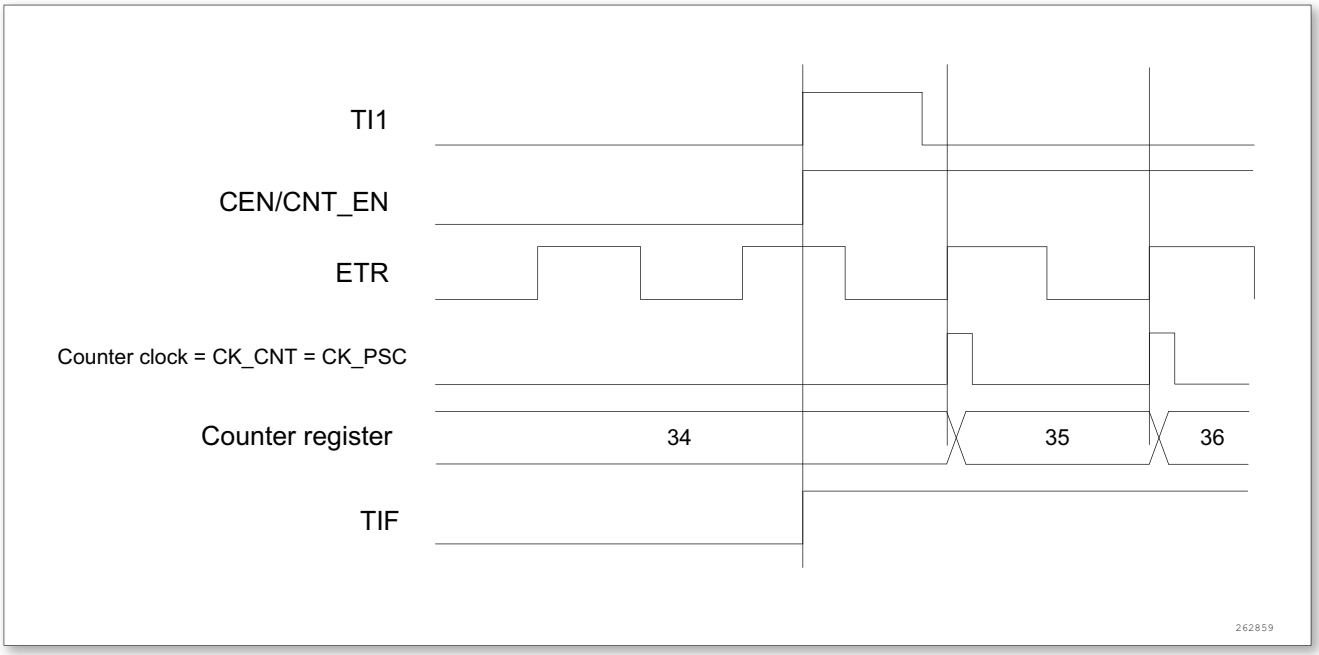

Figure 116. Control Circuit in External Clock Mode 2 + Trigger Mode

12.3.15 Timer synchronization

The TIMx timers are linked together internally for timer synchronization or chaining. When one Timer is configured in Master Mode, it can reset, start, stop or clock the counter of another Timer configured in Slave Mode.

The following figure presents an overview of the trigger selection and the master mode selection blocks.

Using one timer as prescaler for another timer

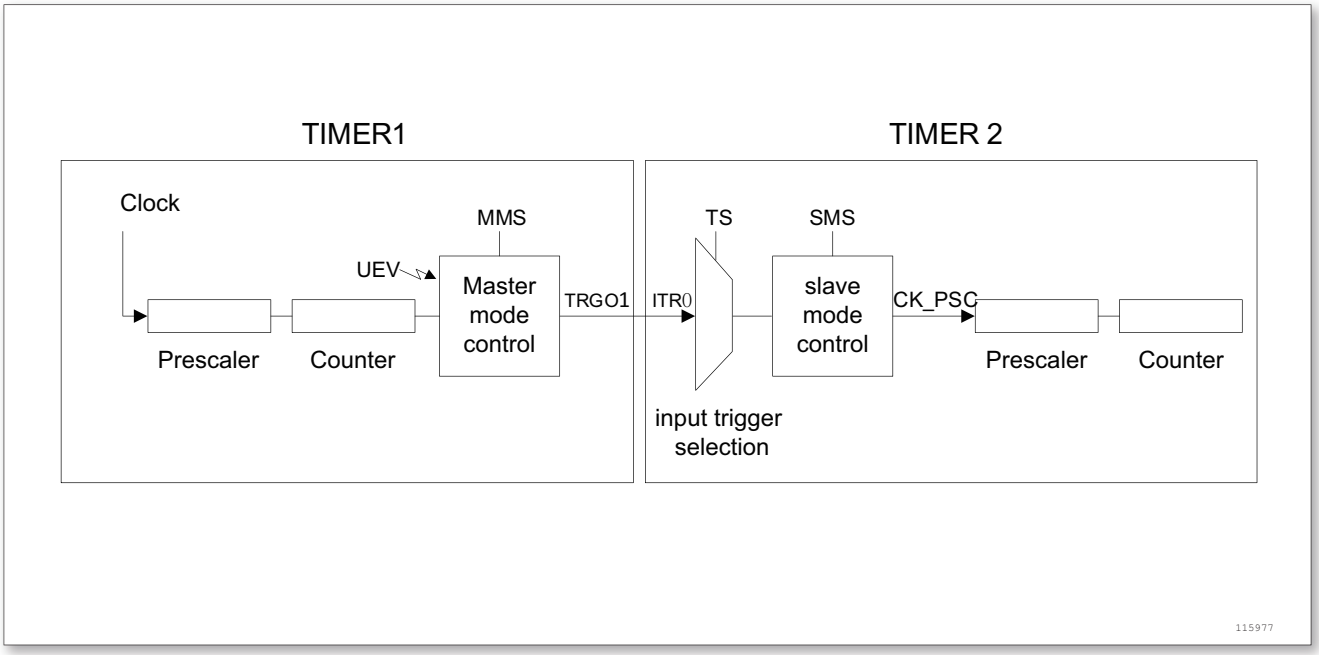

Figure 117. Master/Slave Timer Example

For example, the user can configure Timer 1 to act as a prescaler for Timer 2 (see the above figure). To do this:

- Configure Timer 1 in master mode so that it outputs a periodic trigger signal on each update event UEV. If you write MMS=010 in the TIM1_CR2 register, a rising edge is output on TRGO1 each time an update event is generated.
- To connect the TRGO1 output of Timer 1 to Timer 2, Timer 2 must be configured in slave mode using ITR1 as internal trigger. You select this through the TS bits in the TIM2_SMCR register (writing TS=000).
- Then you put the slave mode controller in external clock mode 1 (write SMS=111 in the TIM2_SMCR register). This causes Timer 2 to be clocked by the rising edge of the periodic Timer 1 trigger signal (which corresponds to the Timer 1 counter overflow).
- Finally, both timers must be enabled by setting their respective CEN bits (TIMx_CR1 register).

Note: If OCx is selected on Timer 1 as trigger output (MMS=1xx), its rising edge is used to clock the counter of Timer 2.

Using one timer to enable another timer

In this example, we control the enable of Timer 2 with the output compare 1 of Timer 1. Refer to the following figure for connections. Timer 2 counts on the divided internal clock only when OC1REF of Timer 1 is high. Both counter clock frequencies are divided by 3 by the prescaler compared to CK_INT ($f_{CK\_CNT} = f_{CK\_INT/3}$).

- Configure Timer 1 master mode to send its Output Compare 1 Reference (OC1REF) signal as trigger output (MMS=100 in the TIM1_CR2 register).
- Configure the Timer 1 OC1REF waveform (TIM1_CCMR1 register).
- Configure Timer 2 to get the input trigger from Timer 1 (TS=001 in the TIM2_SMCR

register).

- Configure Timer 2 in gated mode (SMS=101 in TIM2_SMCR register).
- Enable Timer 2 by writing ‘1 in the CEN bit (TIM2_CR1 register).
- Enable Timer 1 by writing ‘1 in the CEN bit (TIM1_CR1 register).

Note: The counter 2 clock is not synchronized with counter 1, this mode only affects the Timer 2 counter enable signal.

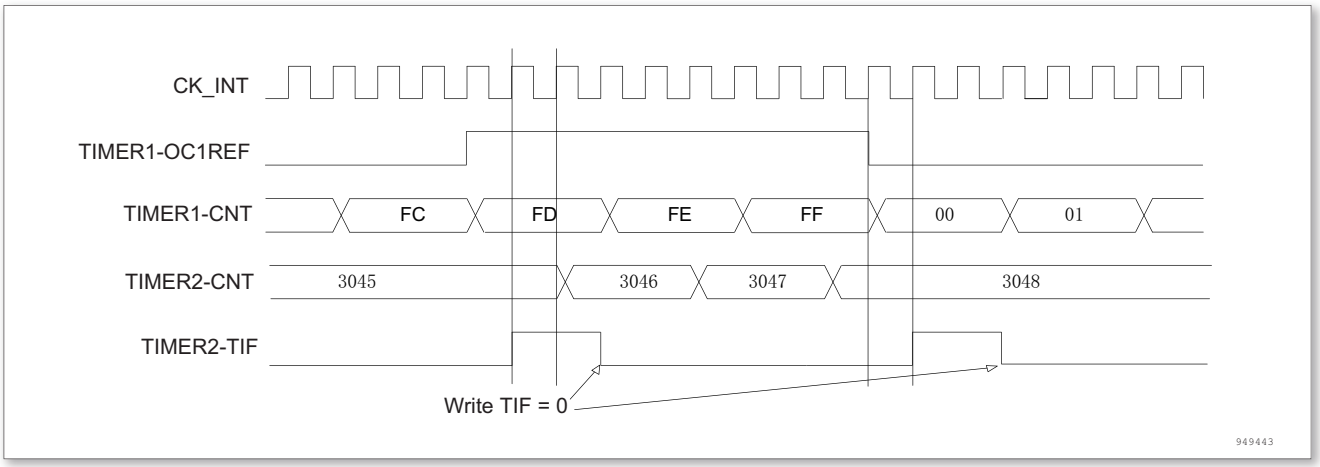

Figure 118. Gating Timer 2 with OC1REF of Timer 1

In the example in the above figure, the Timer 2 counter and prescaler are not initialized before being started. So they start counting from their current value. It is possible to start from a given value by resetting both timers before starting Timer 1. You can then write any value you want in the timer counters. The timers can easily be reset by software using the UG bit in the TIMx_EGR registers.

In the next example, we synchronize Timer 1 and Timer 2. Timer 1 is the master and starts from 0. Timer 2 is the slave and starts from 0xE7. The prescaler ratio is the same for both timers. Timer 2 stops when Timer 1 is disabled by writing ‘0 to the CEN bit in the TIM1_CR1 register:

- Configure Timer 1 master mode to send its Output Compare 1 Reference (OC1REF) signal as trigger output (MMS=100 in the TIM1_CR2 register).
- Configure the Timer 1 OC1REF waveform (TIM1_CCMR1 register).
- Configure Timer 2 to get the input trigger from Timer 1 (TS=000 in the TIM2_SMCR register).
- Configure Timer 2 in gated mode (SMS=101 in TIM2_SMCR register).
- Reset Timer 1 by writing ‘1 in UG bit (TIM1_EGR register).
- Reset Timer 2 by writing ‘1 in UG bit (TIM2_EGR register).
- Initialize Timer 2 to 0xE7 by writing ‘0xE7’ in the Timer 2 counter (TIM2_CNT).
- Enable Timer 2 by writing ‘1 in the CEN bit (TIM2_CR1 register).
- Start Timer 1 by writing ‘1 in the CEN bit (TIM1_CR1 register).
- Stop Timer 1 by writing ‘0 in the CEN bit (TIM1_CR1 register).

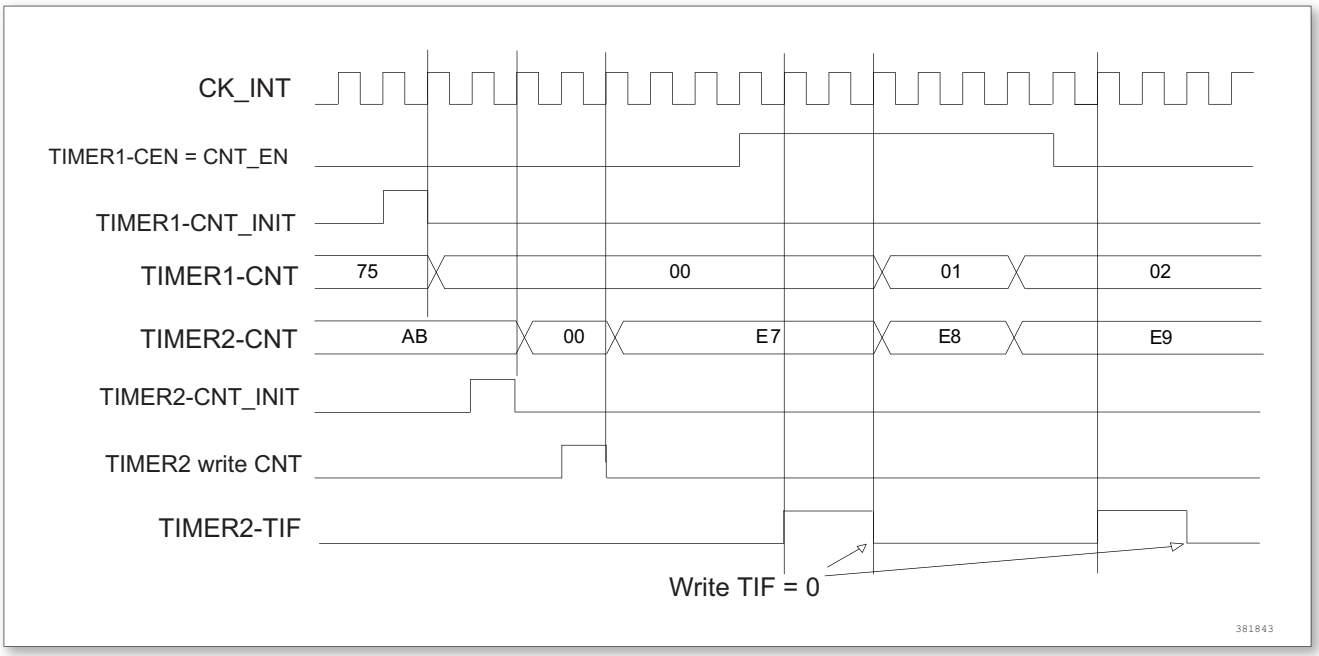

Figure 119. Gating Timer 2 with Enable of Timer 1

Using one timer to start another timer

In this example, we set the enable of Timer 2 with the update event of Timer 1. Refer to the following figure for connections. Timer 2 starts counting from its current value (which can be nonzero) on the divided internal clock as soon as the update event is generated by Timer 1.

When Timer 2 receives the trigger signal its CEN bit is automatically set and the counter counts until we write ’0’ to the CEN bit in the TIM2_CR1 register. Both counter clock frequencies are divided by 3 by the prescaler compared to CK_INT ($f_{CK\_CNT} = f_{CK\_INT/3}$).

- Configure Timer 1 master mode to send its Update Event (UEV) as trigger output (MMS=010 in the TIM1_CR2 register).
- Configure the Timer 1 period (TIM1_ARR registers).
- Configure Timer 2 to get the input trigger from Timer 1 (TS=000 in the TIM2_SMCR register).
- Configure Timer 2 in trigger mode (SMS=110 in TIM2_SMCR register).
- Start Timer 1 by writing ’1’ in the CEN bit (TIM1_CR1 register)

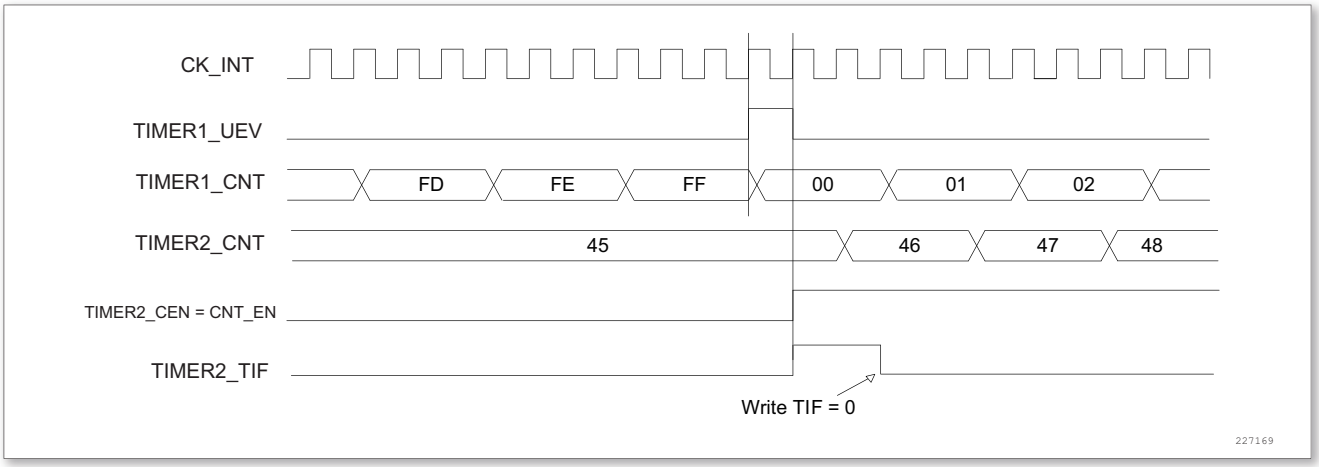

Figure 120. Triggering Timer 2 with Update of Timer 1

As in the previous example, the user can initialize both counters before starting counting. The following figure shows the behavior with the same configuration as ’0’ but in trigger mode instead of gated mode (SMS=110 in the TIM2_SMCR register).

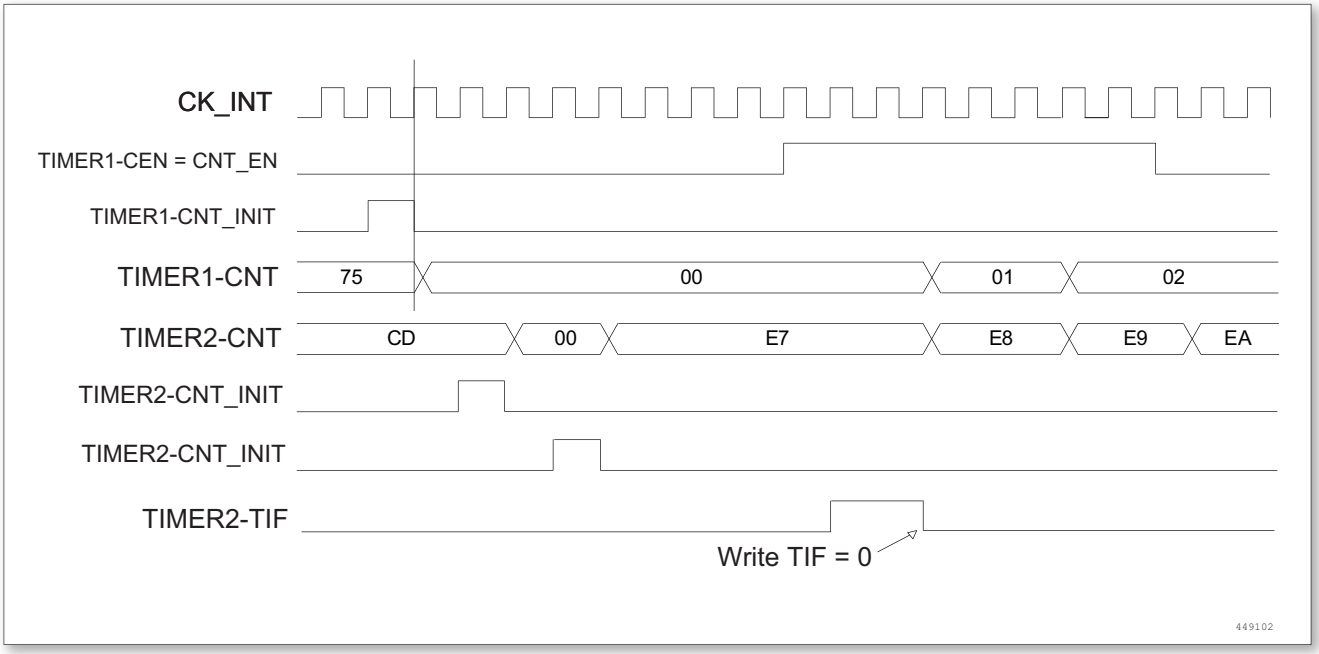

Figure 121. Triggering Timer 2 with Enable of Timer 1

Using one additional timer as prescaler for another timer

In this example, we use Timer 1 as the prescaler for Timer 2. The configuration is as follows:

- Configure Timer 1 in master mode, togenerate the update event (UEV) as the trigger output (MMS=010 in the TIM1_CR2 register). Then, output a periodic signal in case of each counter overflow.
- Configure the Timer 1 period (TIM1_ARR registers).
- Configure Timer 2 to get the input trigger from Timer 1 (TS=000 in the TIM2_SMCR register).
- Configure Timer 2 in the external clock mode (write SMS=111 in the TIM2_SMCR reg-

ister).

- Start Timer 2 by writing ’1’ in the CEN bit (TIM1_CR2 register)
- Start Timer 1 by writing ’1’ in the CEN bit (TIM1_CR1 register).

Starting 2 timers synchronously in response to an external trigger

In this example, we set the enable of timer 1 when its TI1 input rises, and the enable of Timer 2 with the enable of Timer 1. To ensure the counters are aligned, Timer 1 must be configured in Master/Slave mode (slave with respect to TI1, master with respect to Timer 2):

- Configure Timer 1 master mode to send its Enable as trigger output (MMS=001 in the TIM1_CR2 register).
- Configure Timer 1 slave mode to get the input trigger from TI1 (TS=100 in the TIM1_SMCR register).
- Configure Timer 1 in trigger mode (SMS=110 in the TIM1_SMCR register).
- Configure Timer 2 to get the input trigger from Timer 1 (TS=000 in the TIM2_SMCR register).
- Configure Timer 2 in trigger mode (SMS=110 in the TIM2_SMCR register).

When a rising edge occurs on TI1 (Timer 1), both counters starts counting synchronously on the internal clock and both TIF flags are set. Note: In this example both timers are initialized before starting (by setting their respective UG bits). Both counters starts from 0, but you can easily insert an offset between them by writing any of the counter registers (TIMx_CNT). You can see that the master/slave mode insert a delay between CNT_EN and CK_PSC on timer 1.

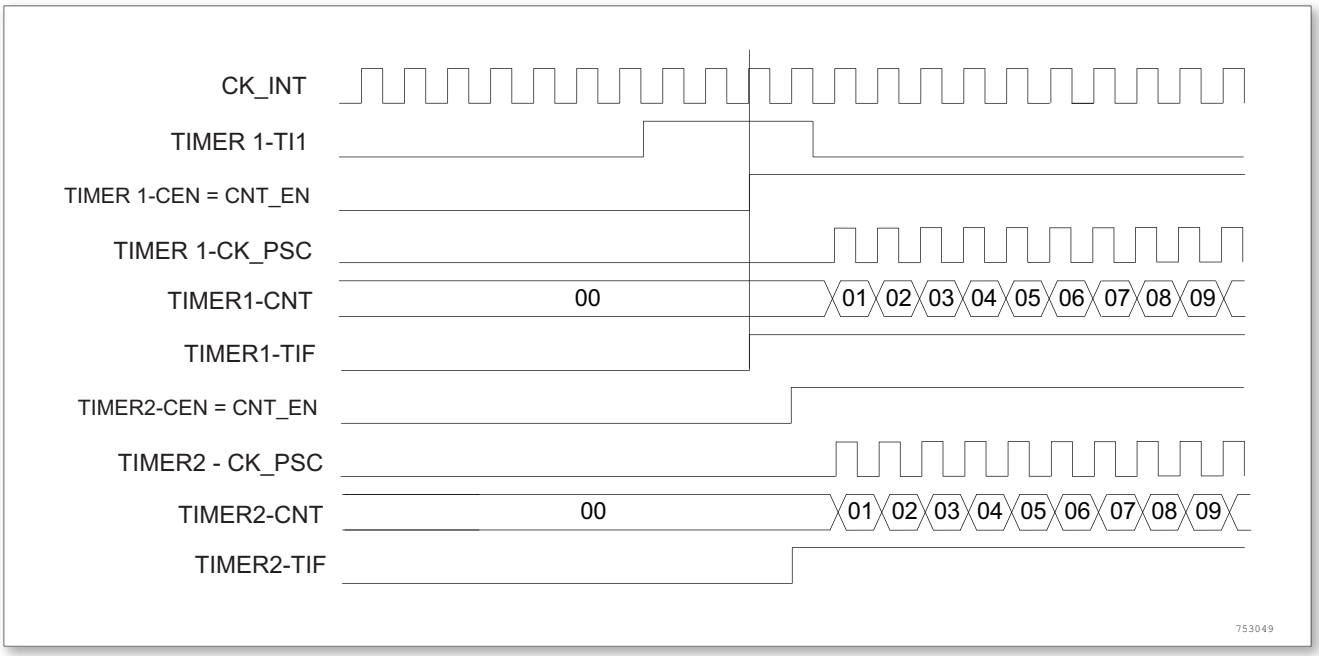

Figure 122. Triggering Timer 1 and 2 with Timer 1 TI1 input

12.3.16 Debug mode

When the microcontroller enters debug mode (CPU core - halted), the TIMx counter either continues to work normally or stops, depending on DBG_TIMx_STOP configuration bit in

DBG module. For more details, refer to ”Debug” sections.

12.4 TIMx register description

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

Bit	Field	Type	Reset	Description
9: 8	CKD	rw	0x00	Clock division The 2 bits indicates the division ratio between the timer clock (CK_INT) frequency and the dead-time and sampling clock used by the dead-time generators and the digital filters (ETR, TIx). 00: $t_{DTS} = t_{CK\_INT}$ 01: $t_{DTS} = 2 \times t_{CK\_INT}$ 10: $t_{DTS} = 4 \times t_{CK\_INT}$ 11: Reserved, do not program this value
7	ARPE	rw	0x00	Auto-reload preload enable 0: TIMx_ARR register is not buffered 1: TIMx_ARR register is buffered
6: 5	CMS	rw	0x00	Center-aligned mode selection 00: Edge-aligned mode. The counter counts up or down depending on the direction bit (DIR). 01: Center-aligned mode 1. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set only when the counter is counting down. 10: Center-aligned mode 2. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set only when the counter is counting up. 11: Center-aligned mode 3. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set both when the counter is counting up or down. Note: It is not allowed to switch from edge-aligned mode to center-aligned mode as long as the counter is enabled (CEN=1).
4	DIR	rw	0x00	Direction 0: Counter used as upcounter 1: Counter used as downcounter Note: This bit is read only when the timer is configured in Center-aligned mode or Encoder mode.
3	OPM	rw	0x00	One pulse mode 0: Counter is not stopped at update event 1: Counter stops counting at the next update event (clearing the bit CEN)

Bit	Field	Type	Reset	Description
2	URS	rw	0x00	Update request source This bit is set and cleared by software to select the UEV event sources. 0: Any of the following events generates an update interrupt or DMA request if enabled.These events can be: - Counter overflow/underflow - Setting the UG bit - Update generation through the slave mode controller 1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.
1	UDIS	rw	0x00	Update disable This bit is set and cleared by software to enable/disable UEV event generation. 0: UEV enabled. The Update (UEV) event is generated by one of the following events: - Counter overflow/underflow - Setting the UG bit - Update generation through the slave mode controller, buffered registers are then loaded with their preload values 1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.
0	CEN	rw	0x00	Counter enable 0: Counter disabled 1: Counter enabled Note: External clock, gated mode and encoder mode can work only if the CEN bit has been previously set by software. However, trigger mode can set the CEN bit automatically by hardware.

12.4.2 Control register 2(TIMx_CR2)

Offset address: 0x04

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								TI1S	MMS			CCDS	Reserved		
								rw	rw	rw	rw	rw			

Bit	Field	Type	Reset	Description
15: 8	Reserved			Reserved, always read as 0.
7	TI1S	rw	0x00	TI1 selection 0: The TIMx_CH1 pin is connected to TI1 input 1: The TIMx_CH1, CH2 and CH3 pins are connected to the TI1 input (XOR combination)
6: 4	MMS	rw	0x00	Master mode selection These bits allow to select the information to be sent in master mode to slave timers for synchronization (TRGO). The combination is as follows: 000: Reset - the UG bit from the TIMx_EGR register is used as trigger output (TRGO). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on TRGO is delayed compared to the actual reset. 001: Enable - the Counter Enable signal CNT_EN is used as trigger output (TRGO). It is useful to start several timers at the same time or to control a window in which a slave timer is enable. The Counter Enable signal is generated by a logic OR between CEN control bit and the trigger input when configured in gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on TRGO, except if the master/slave mode is selected (see the MSM bit description in TIMx_SMCR register). 010: Update - The update event is selected as trigger output (TRGO). For instance, a master timer can then be used as a prescaler for a slave timer. 011: Compare Pulse - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred (TRGO). 100: Compare - OC1REF signal is used as trigger output (TRGO) 101: Compare - OC2REF signal is used as trigger output (TRGO) 110: Compare - OC3REF signal is used as trigger output (TRGO) 111: Compare - OC4REF signal is used as trigger output (TRGO)
3	CCDS	rw	0x00	Capture/compare DMA selection 0: CCx DMA request sent when CCx event occurs 1: CCx DMA requests sent when update event occurs

Bit	Field	Type	Reset	Description
2: 0	Reserved			Reserved, always read as 0.

12.4.3 Slave mode control register(TIMx_SMCR)

Offset address: 0x08

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ETP	ECE	ETPS		ETF				MSM	TS			Res.	SMS		
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		rw	rw	rw

Bit	Field	Type	Reset	Description
15	ETP	rw	0x00	External trigger polarity This bit selects whether ETR or inverted ETR is used for trigger operations. 0: ETR is non-inverted, active at high level or rising edge. 1: ETR is inverted, active at low level or falling edge.
14	ECE	rw	0x00	External clock enable This bit enables External clock mode 2. 0: External clock mode 2 disabled 1: External clock mode 2 enabled. The counter is clocked by any active edge on the ETRF signal. Note 1: Setting the ECE bit has the same effect as selecting external clock mode 1 with TRGI connected to ETRF (SMS=111 and TS=111). Note 2: It is possible to simultaneously use external clock mode 2 with the following slave modes: reset mode, gated mode and trigger mode. Nevertheless, TRGI must not be connected to ETRF in this case (TS bits must not be 111). Note 3: If external clock mode 1 and external clock mode 2 are enabled at the same time, the external clock input is ETRF.
13: 12	ETPS	rw	0x00	External trigger prescaler External trigger signal ETRP frequency must be at most 1/4 of TIMxCLK frequency. A prescaler can be enabled to reduce ETRP frequency. It is useful when inputting fast external clocks. 00: Prescaler OFF 01: ETRP frequency divided by 2 10: ETRP frequency divided by 4 11: ETRP frequency divided by 8

Bit	Field	Type	Reset	Description
11: 8	ETF	rw	0x00	External trigger filter This bit-field then defines the frequency used to sample ETRP signal and the length of the digital filter applied to ETRP. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output: 0000: No filter, sampling is done at f_{DTS}. 0001: sampling frequency $f_{SAMPLING}=f_{CK\_INT}$, N = 2 0010: sampling frequency $f_{SAMPLING}=f_{CK\_INT}$, N = 4 0011: sampling frequency $f_{SAMPLING}=f_{CK\_INT}$, N = 8 0100: sampling frequency $f_{SAMPLING}=f_{DTS}/2$, N = 6 0101: sampling frequency $f_{SAMPLING}=f_{DTS}/2$, N = 8 0110: sampling frequency $f_{SAMPLING}=f_{DTS}/4$, N = 6 0111: sampling frequency $f_{SAMPLING}=f_{DTS}/4$, N = 8 1000: sampling frequency $f_{SAMPLING}=f_{DTS}/8$, N = 6 1001: sampling frequency $f_{SAMPLING}=f_{DTS}/8$, N = 8 1010: sampling frequency $f_{SAMPLING}=f_{DTS}/16$, N = 5 1011: sampling frequency $f_{SAMPLING}=f_{DTS}/16$, N = 6 1100: sampling frequency $f_{SAMPLING}=f_{DTS}/16$, N = 8 1101: sampling frequency $f_{SAMPLING}=f_{DTS}/32$, N = 5 1110: sampling frequency $f_{SAMPLING}=f_{DTS}/32$, N = 6 1111: sampling frequency $f_{SAMPLING}=f_{DTS}/32$, N = 8
7	MSM	rw	0x00	Master/slave mode 0: No action 1: The effect of an event on the trigger input (TRGI) is delayed to allow a perfect synchronization between the current timer and its slaves (through TRGO). It is useful if we want to synchronize several timers on a single external event.

Bit	Field	Type	Reset	Description
6: 4	TS	rw	0x00	Trigger selection This bit-field selects the trigger input to be used to synchronize the counter. 000: Internal Trigger 0 (ITR0) 001: Internal Trigger 1(ITR1) 010: Internal Trigger 2(ITR2) 011: Internal Trigger 3(ITR3) 100: TI1 Edge Detector (TI1F_ED) 101: Filtered Timer Input 1 (TI1FP1) 110: Filtered Timer Input 2(TI2FP2) 111: External Trigger input (ETRF) See the following table for more details on ITRx. Note: These bits must be changed only when they are not used (e.g. when SMS=000) to avoid wrong edge detections at the transition.
3	Reserved			Reserved, always read as 0.

Bit	Field	Type	Reset	Description
2: 0	SMS	rw	0x00	Slave mode selection When external signals are selected the active edge of the trigger signal (TRGI) is linked to the polarity selected on the external input (refer to Input Control register and Control Register description). 000: Slave mode disabled - if CEN = '1' then the prescaler is clocked directly by the internal clock. 001: Encoder mode 1 - Counter counts up/down on TI2FP1 edge depending on TI1FP2 level. 010: Encoder mode 2 - Counter counts up/down on TI1FP2 edge depending on TI2FP1 level. 011: Encoder mode 3 - Counter counts up/down on both TI1FP1 and TI2FP2 edges depending on the level of the other input. 100: Reset Mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter and generates an update of the registers. 101: Gated Mode - The counter clock is enabled when the trigger input (TRGI) is high. The counter stops (but is not reset) as soon as the trigger input becomes low. Both start and stop of the counter are controlled. 110: Trigger Mode - The counter starts at a rising edge of the trigger TRGI (but it is not reset). Only the start of the counter is controlled. 111: External Clock Mode 1 - Rising edges of the selected trigger input (TRGI) clock the counter. Note: The gated mode must not be used if TI1F_EN is selected as the trigger input (TS= '100'). Indeed, TI1F_ED outputs 1 pulse for each transition on TI1F, whereas the gated mode checks the level of the trigger signal.

			rc_w0	rc_w0	rc_w0	rc_w0			rc_w0		rc_w0	rc_w0	rc_w0	rc_w0	rc_w0

Bit	Field	Type	Reset	Description
15: 13	Reserved			Reserved, always read as 0.
12	CC4OF	rc_w0	0x00	Capture/Compare 4 overcapture flag Refer to CC1OF description.
11	CC3OF	rc_w0	0x00	Capture/Compare 3 overcapture flag Refer to CC1OF description.
10	CC2OF	rc_w0	0x00	Capture/Compare 2 overcapture flag Refer to CC1OF description.
9	CC1OF	rc_w0	0x00	Capture/Compare 1 overcapture flag This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to ‘0’. 0: No overcapture has been detected. 1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set.
8: 7	Reserved			Reserved, always read as 0.
6	TIF	rc_w0	0x00	Trigger interrupt flag This flag is set by hardware on trigger event (active edge detected on TRGI input when the slave mode controller is enabled in all modes but gated mode, both edges in case gated mode is selected). It is cleared by software. 0: No trigger event occurred. 1: Trigger interrupt pending.
5	Reserved			Reserved, always read as 0.
4	CC4IF	rc_w0	0x00	Capture/Compare 4 interrupt flag Refer to CC1IF description.
3	CC3IF	rc_w0	0x00	Capture/Compare 3 interrupt flag Refer to CC1IF description.
2	CC2IF	rc_w0	0x00	Capture/Compare 2 interrupt flag Refer to CC1IF description.

Bit	Field	Type	Reset	Description
1	CC1IF	rc_w0	0x00	Capture/Compare 1 interrupt flag If channel CC1 is configured as output: This flag is set by hardware when the counter matches the compare value, with some exception in center-aligned mode (refer to the CMS bits in the TIMx_CR1 register description). It is cleared by software. 0: No match 1: The content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register. If channel CC1 is configured as input: This bit is set by hardware on a capture. It is cleared by software or by reading the TIMx_CCR1 register. 0: No input capture occurred 1: The counter value has been captured in TIMx_CCR1 register (An edge has been detected on IC1 which matches the selected polarity)
0	UIF	rc_w0	0x00	Update interrupt flag This bit is set by hardware on an update event. It is cleared by software. 0: No update occurred. 1: Update interrupt pending. This bit is set by hardware when the registers are updated: - At overflow or underflow regarding the repetition counter value (update if repetition counter= 0) and if the UDIS=0 in the TIMx_CR1 register. – When CNT is reinitialized by software using the UG bit in TIMx_EGR register, if URS=0 and UDIS=0 in the TIMx_CR1 register. –When CNT is reinitialized by a trigger event (refer to the description of synchronization control register), if URS=0 and UDIS=0 in the TIMx_CR1 register.

12.4.6 Event generation register (TIMx_EGR)

Offset address: 0x14

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.									TG	Res.	CC4G	CC3G	CC2G	CC1G	UG
									w		w	w	w	w	w

Bit	Field	Type	Reset	Description
15: 7	Reserved			Reserved, always read as 0.

Bit	Field	Type	Reset	Description
6	TG	w	0x00	Trigger generation This bit is set by software in order to generate an event, it is automatically cleared by hardware. 0: No action 1: The TIF flag is set in TIMx_SR register. Related interrupt or DMA transfer can occur if enabled.
5	Reserved			Reserved, always read as 0.
4	CC4G	w	0x00	Capture/Compare 4 generation Refer to CC1G description.
3	CC3G	w	0x00	Capture/Compare 3 generation Refer to CC1G description.
2	CC2G	w	0x00	Capture/Compare 2 generation Refer to CC1G description.
1	CC1G	w	0x00	Capture/Compare 1 generation This bit is set by software in order to generate an event, it is automatically cleared by hardware. 0: No action 1: A capture/compare event is generated on channel 1: If channel CC1 is configured as output: CC1IF flag is set, Corresponding interrupt or DMA request is sent if enabled. If channel CC1 is configured as input: The current value of the counter is captured in TIMx_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.
0	UG	w	0x00	Update generation This bit can be set by software, it is automatically cleared by hardware. 0: No action 1: Reinitialize the counter and generate an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler factor is not affected). The counter is cleared if the center-aligned mode is selected or if DIR=0 (upcounting), otherwise, it takes the auto-reload value (TIMx_ARR) if DIR=1 (downcounting).

12.4.7 Capture/compare mode register 1(TIMx_CCMR1)

Offset address: 0x18

Reset value: 0x0000

The channels can be used in input (capture mode) or in output (compare mode). The

direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode. For a given bit, OCxx describes its function when the channel is configured in output, ICxx describes its function when the channel is configured in input. So the user must take care that the same bit can have a different meaning for the input stage and for the output stage.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OC2CE	OC2M			OC2PE	OC2FE	CC2S		OC1CE	OC1M			OC1PE	OC1FE	CC1S	
IC2F				IC2PSC				IC1F				IC1PSC			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Output compare mode:

Bit	Field	Type	Reset	Description
15	OC2CE	rw	0x00	Output compare 2 clear enable
14: 12	OC2M	rw	0x00	Output compare 2 mode
11	OC2PE	rw	0x00	Output compare 2 preload enable
10	OC2FE	rw	0x00	Output compare 4 fast enable
9: 8	CC2S	rw	0x00	Capture/Compare 2 selection This bit-field defines the direction of the channel (input/output) as well as the input pin. 00: CC2 channel is configured as output 01: CC2 channel is configured as input, IC2 is mapped on TI2 10: CC2 channel is configured as input, IC2 is mapped on TI1 11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through the TS bit (TIMx_SMCR register) Note: CC2S bits are writable only when the channel is OFF (CC2E = ‘0’ in TIMx_CCER).
7	OC1CE	rw	0x00	Output compare 1 clear enable 0: OC1Ref is not affected by the ETRF Input 1: OC1Ref is cleared as soon as a High level is detected on ETRF input

Bit	Field	Type	Reset	Description
6: 4	OC1M	rw	0x00	Output compare 1 mode These bits define the behavior of the output reference signal OC1REF from which OC1 and OC1N are derived. OC1REF is active high whereas OC1 and OC1N active level depends on CC1P and CC1NP bits. 000: Frozen - The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs 001: Set channel 1 to active level on match. OC1REF signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1). 010: Set channel 1 to inactive level on match. OC1REF signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1). 011: Toggle - OC1REF toggles when TIMx_CNT=TIMx_CCR1. 100: Force inactive level - OC1REF is forced low. 101: Force active level - OC1REF is forced high. 110: PWM mode 1 - In upcounting, channel 1 is active as long as TIMx_CNT<TIMx_CCR1 otherwise inactive. In downcounting, channel 1 is inactive (OC1REF=‘0’) as long as TIMx_CNT>TIMx_CCR1 otherwise active (OC1REF=’1’). 111: PWM mode 2 - In upcounting, channel 1 is inactive as long as TIMx_CNT<TIMx_CCR1otherwise active. In downcounting, channel 1 is active as long as TIMx_CNT>TIMx_CCR1 otherwise inactive. Note 1: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S=’00’(the channel is configured in output). Note 2: In PWM mode 1 or 2, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from “frozen” mode to “PWM” mode.

Bit	Field	Type	Reset	Description
3	OC1PE	rw	0x00	Output compare 1 preload enable 0: Preload register on TIMx_CCR1 disabled. TIMx_CCR1 can be written at anytime, the new value is taken in account immediately. 1: Preload register on TIMx_CCR1 enabled. Read/Write operations access the preload register. TIMx_CCR1 preload value is loaded in the active register at each update event. Note 1: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S=’00’ (the channel is configured in output). Note 2: The PWM mode can be used without validating the preload register only in one pulse mode (OPM bit set in TIMx_CR1 register). Else the behavior is not guaranteed.
2	OC1FE	rw	0x00	Output compare 1 fast enable This bit is used to accelerate the effect of an event on the trigger in input on the CC output. 0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles. 1: An active edge on the trigger input acts like a compare match on CC1 output. Then, OC is set to the compare level independently from the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OCFE acts only if the channel is configured in PWM1 or PWM2 mode.
1: 0	CC1S	rw	0x00	Capture/Compare 1 selection This bit-field defines the direction of the channel (input/output) as well as the input pin. 00: CC1 channel is configured as output 01: CC1 channel is configured as input, IC1 is mapped on TI1 10: CC1 channel is configured as input, IC1 is mapped on TI2 11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register) Note: CC1S bits are writable only when the channel is OFF (CC1E = ’0’ in TIMx_CCER).

Input capture mode:

Bit	Field	Type	Reset	Description
15: 12	IC2F	rw	0x00	Input capture 2 filter
11: 10	IC2PSC	rw	0x00	Input capture 2 prescaler
9: 8	CC2S	rw	0x00	Capture/Compare 2 selection This bit-field defines the direction of the channel (input/output) as well as the input pin. 00: CC2 channel is configured as output 01: CC2 channel is configured as input, IC2 is mapped on TI2 10: CC2 channel is configured as input, IC2 is mapped on TI1 11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through the TS bit (TIMx_SMCR register) Note: CC2S bits are writable only when the channel is OFF (CC2E = '0' in TIMx_CCER).
7: 4	IC1F	rw	0x00	Input capture 1 filter This bit-field defines the frequency used to sample TI1 input and the length of the digital filter applied to TI1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output: 0000: No filter, sampling is done at f_{DTS} 1000: sampling frequency $f_{SAMPLING}=f_{DTS}/8$, N = 6 0001: sampling frequency $f_{SAMPLING}=f_{CK\_INT}$, N = 2 1001: sampling frequency $f_{SAMPLING}=f_{DTS}/8$, N = 8 0010: sampling frequency $f_{SAMPLING}=f_{CK\_INT}$, N = 4 1010: sampling frequency $f_{SAMPLING}=f_{DTS}/16$, N = 5 0011: sampling frequency $f_{SAMPLING}=f_{CK\_INT}$, N = 8 1011: sampling frequency $f_{SAMPLING}=f_{DTS}/16$, N = 6 0100: sampling frequency $f_{SAMPLING}=f_{DTS}/2$, N = 6 1100: sampling frequency $f_{SAMPLING}=f_{DTS}/16$, N = 8 0101: sampling frequency $f_{SAMPLING}=f_{DTS}/2$, N = 8 1101: sampling frequency $f_{SAMPLING}=f_{DTS}/32$, N = 5 0110: sampling frequency $f_{SAMPLING}=f_{DTS}/4$, N = 6 1110: sampling frequency $f_{SAMPLING}=f_{DTS}/32$, N = 6 0111: sampling frequency $f_{SAMPLING}=f_{DTS}/4$, N = 8 1111: sampling frequency $f_{SAMPLING}=f_{DTS}/32$, N = 8

Bit	Field	Type	Reset	Description
3: 2	IC1PSC	rw	0x00	Input capture 1 prescaler This bit-field defines the factor of the prescaler acting on CC1 input (IC1). The prescaler is reset as soon as CC1E=’0’(TIMx_CCER register). 00: no prescaler, capture is done each time an edge is detected on the capture input. 01: capture is done once every 2 events 10: capture is done once every 4 events 11: capture is done once every 8 events
1: 0	CC1S	rw	0x00	Capture/compare 1 selection This bit-field defines the direction of the channel (input/output) as well as the input pin. 00: CC1 channel is configured as output 01: CC1 channel is configured as input, IC1 is mapped on TI1 10: CC1 channel is configured as input, IC1 is mapped on TI2 11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through the TS bit (TIMx_SMCR register) Note: CC1S bits are writable only when the channel is OFF (CC1E = ‘0’ in TIMx_CCER).

13 32-bit general-purpose timers (TIMx32 Bit)

32-bit general-purpose timers (TIMx32 Bit)

13.1 TIMx introduction

General-purpose timers consist of a 32-bit auto-reload counter driven by a programmable prescaler.

It may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare and PWM).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

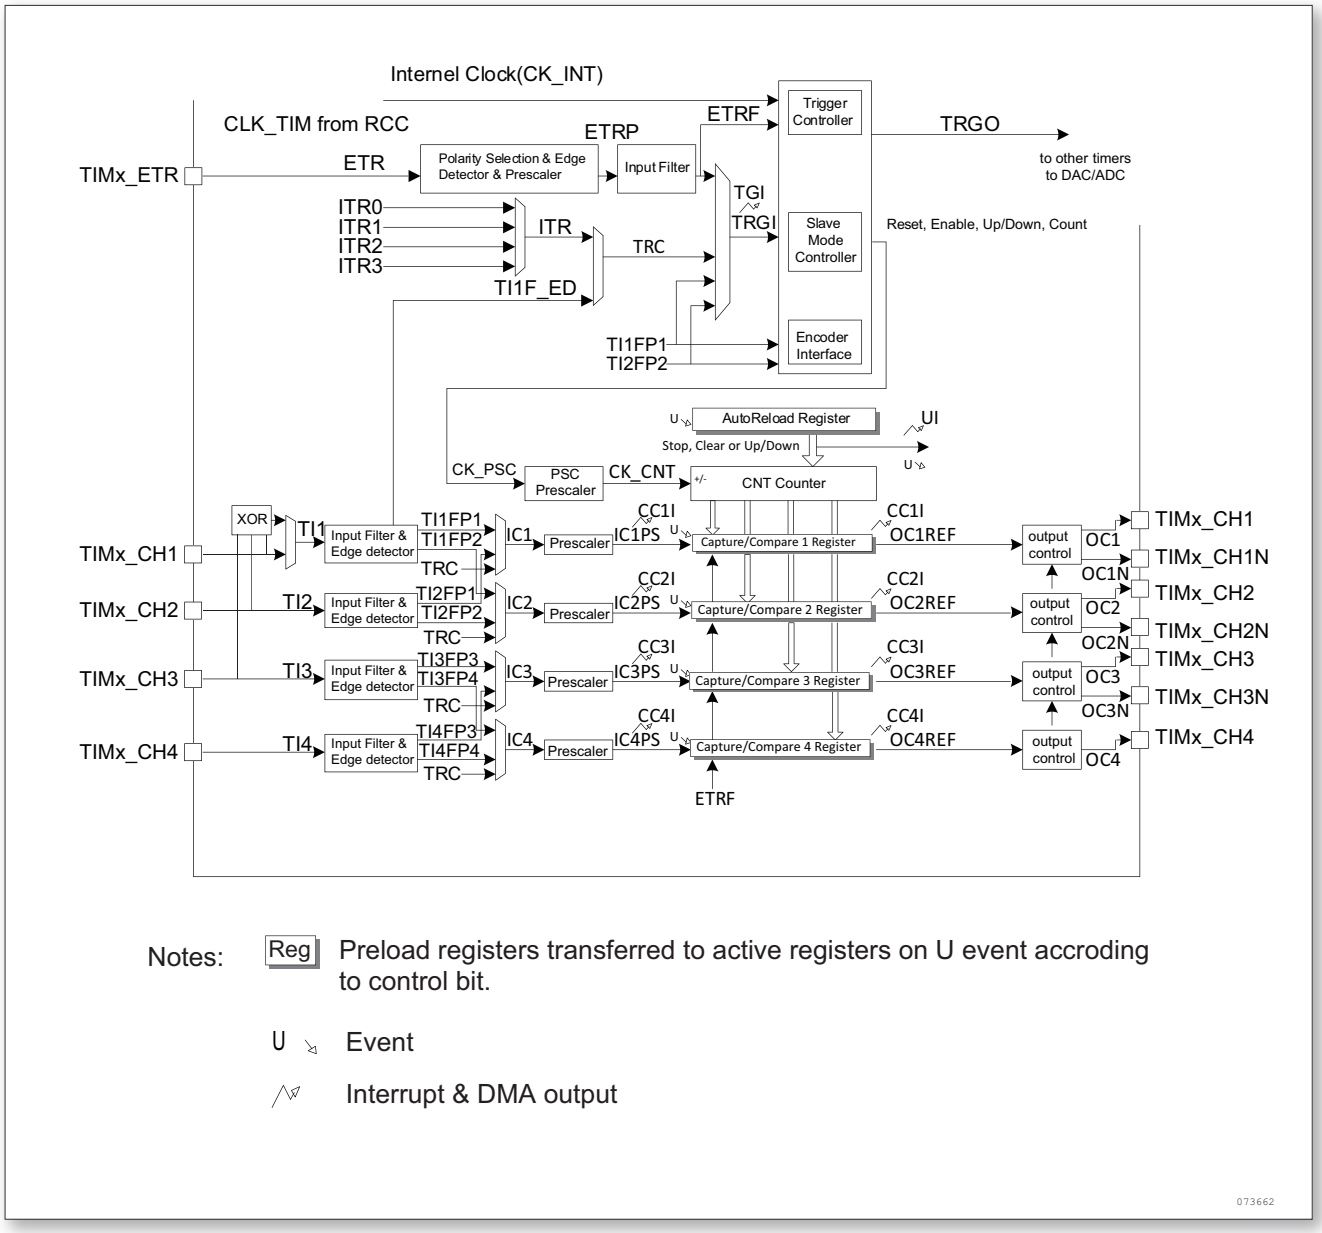
TIMx are completely independent, and do not share any resources. They can be synchronized together as described in Section Timer Synchronization.

13.2 TIMx Main features

TIM2 functions include:

- 32-bit up, down, up/down auto-reload register
- 16-bit programmable prescaler allowing dividing (modifing in real time) the counter clock frequency either by any factor between 1 and 65536.
- Up to 4 independent channels for:
  - Input capture
  - Output compare
  - PWM generation (Edge and Center-aligned Mode)
  - One-pulse mode output
- circuit to control the timer with external signals and to interconnect several timers together.
- Interrupt/DMA generation on the following events:
  - Update: counter overflow/underflow, counter initialization (by software or internal/external trigger)
  - Trigger event (counter start, stop, initialization or count by internal/external trigger)
  - Input capture
  - Output compare
- Supports incremental (quadrature) encoder and hall-sensor circuitry for positioning purposes

- Trigger input for external clock or cycle-by-cycle current management



Notes: Reg Preload registers transferred to active registers on U event accroding to control bit.

Figure 123. Block Diagram of general-purpose timer

13.3 TIMx Functional description

13.3.1 Time-base unit

The main block of the programmable general-purpose timer is a 32-bit counter with its related auto-reload register. The counter can count up, down or both up and down. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running. The time-base unit includes:

- Counter register (TIMx_CNT)
- Prescaler register (TIMx_PSC)

- Auto-reload register (TIMx_ARR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter reaches the overflow (or underflow when downcounting) and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in details for each configuration.

The counter is clocked by the prescaler output CK_CNT, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 32-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler factor is taken into account at the next update event.

The following figures give some examples of the counter behavior when the prescaler factor is changed on the fly:

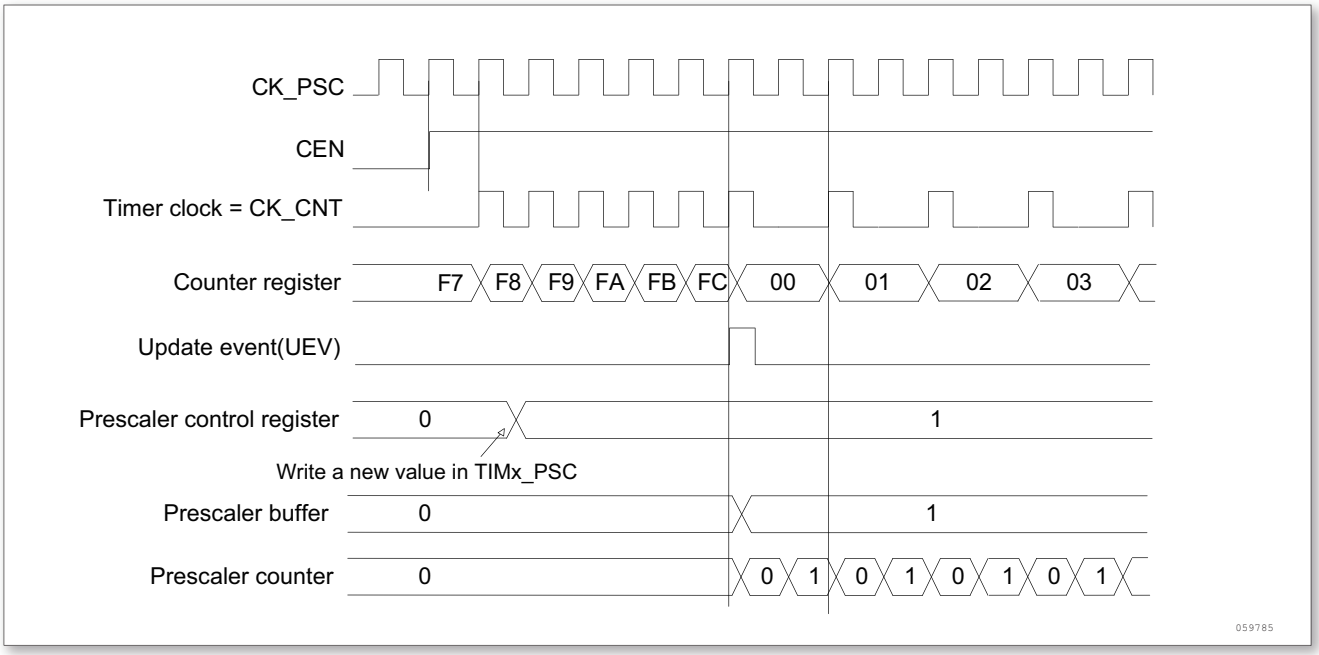

Figure 124. Counter Timing Diagram with Prescaler Division Change from 1 to 2

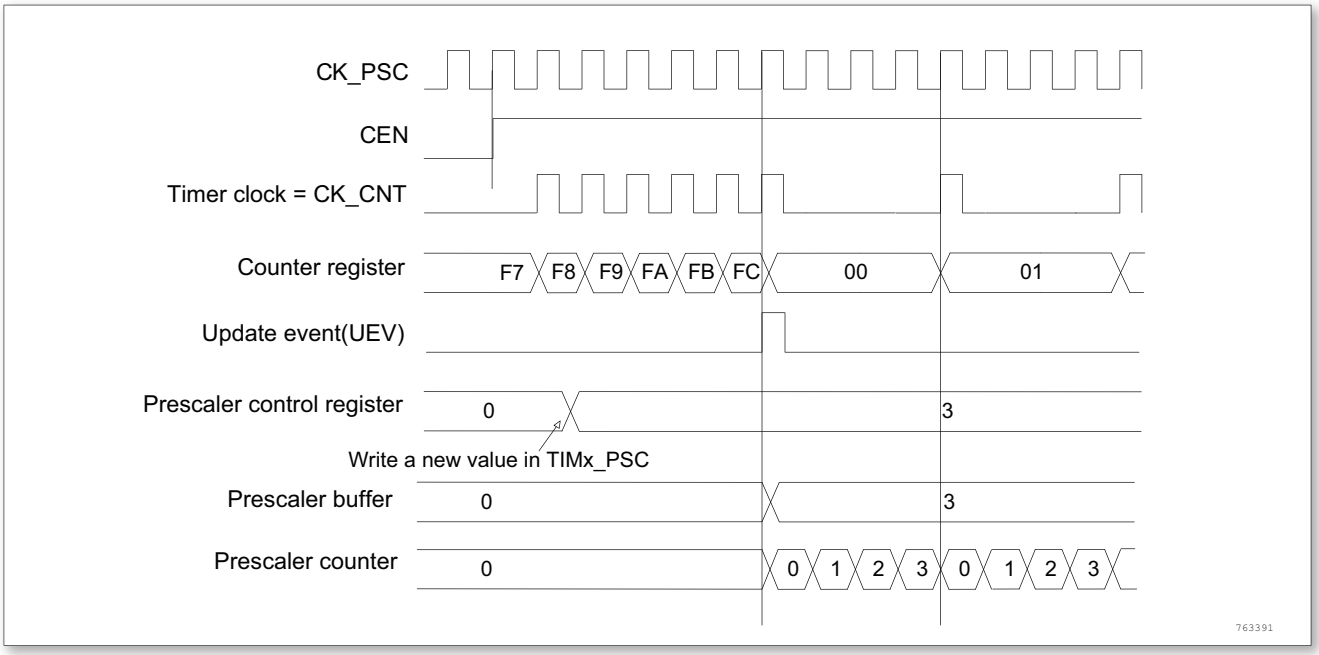

Figure 125. Counter Timing Diagram with Prescaler Division Change from 1 to 4

13.3.2 Counter modes

Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

An Update event can be generated at each counter overflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller).

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change).

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag bit(UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).
- The auto-reload shadow register is updated with the preload value (TIMx_ARR).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR = 0x36.

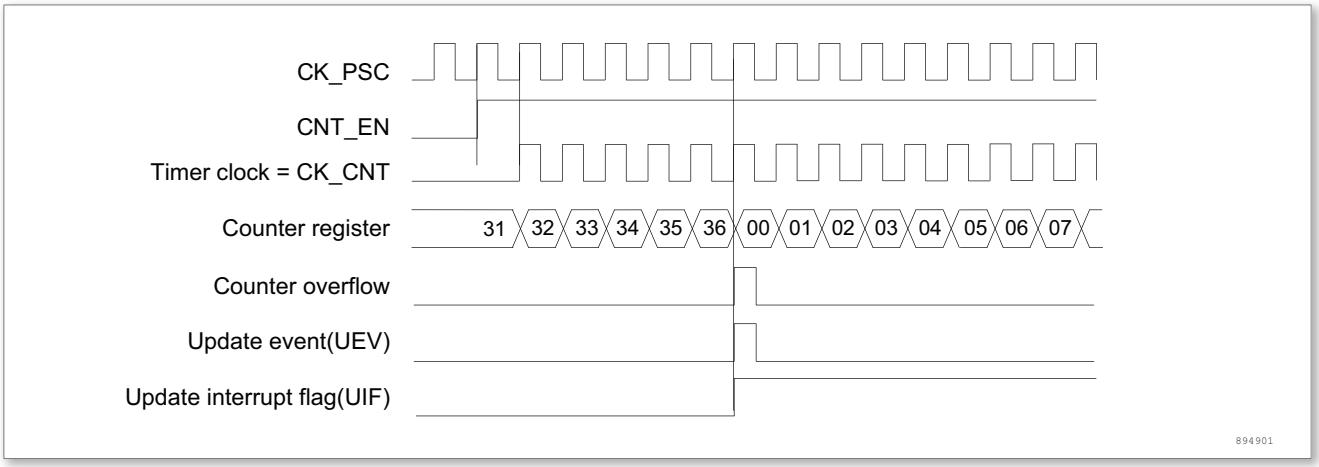

Figure 126. Counter Timing Diagram, Internal Clock Divided by 1

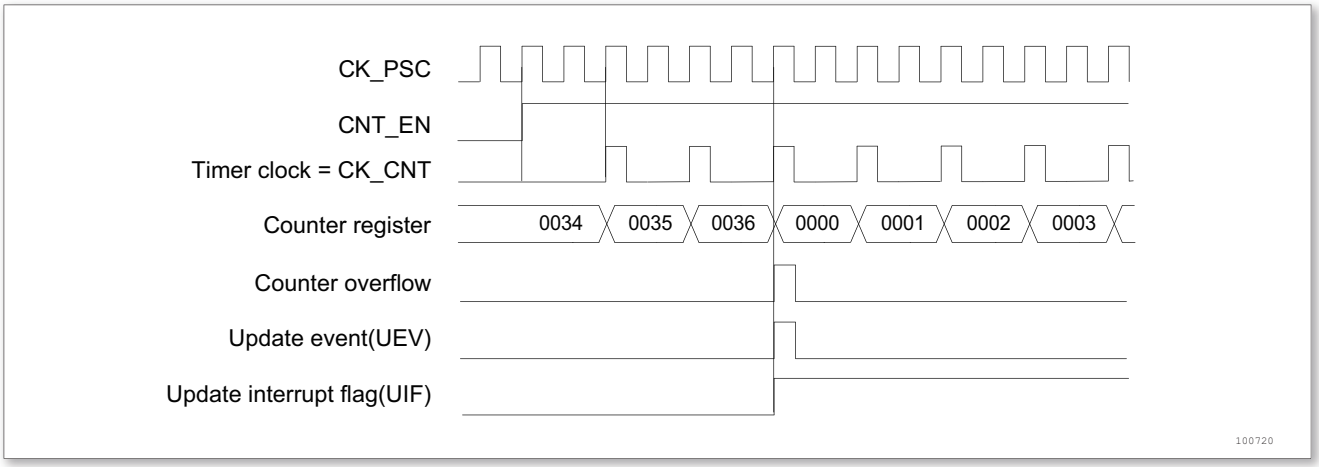

Figure 127. Counter Timing Diagram, Internal Clock Divided by 2

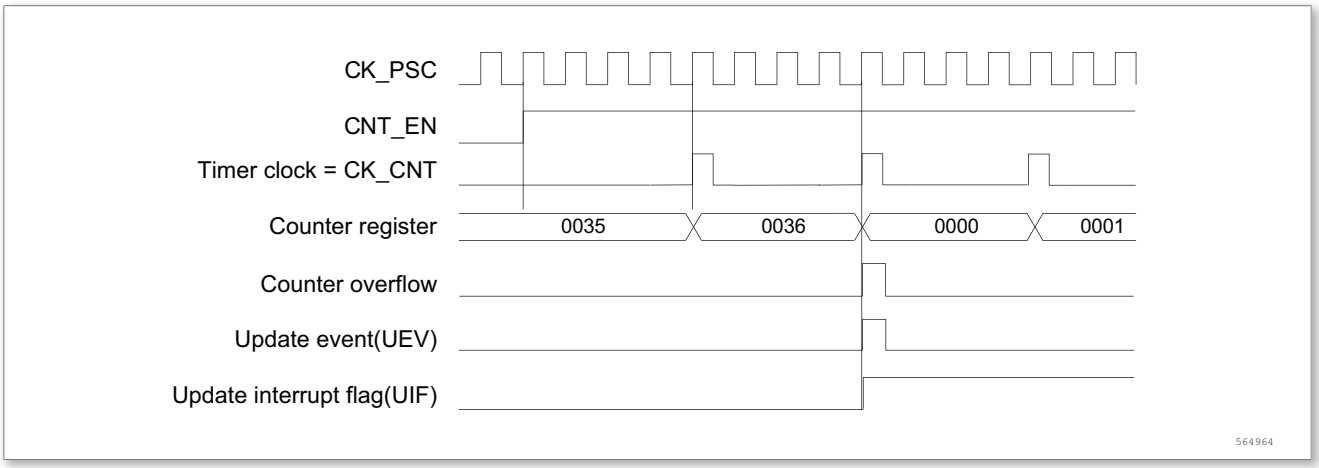

Figure 128. Counter Timing Diagram, Internal Clock Divided by 4

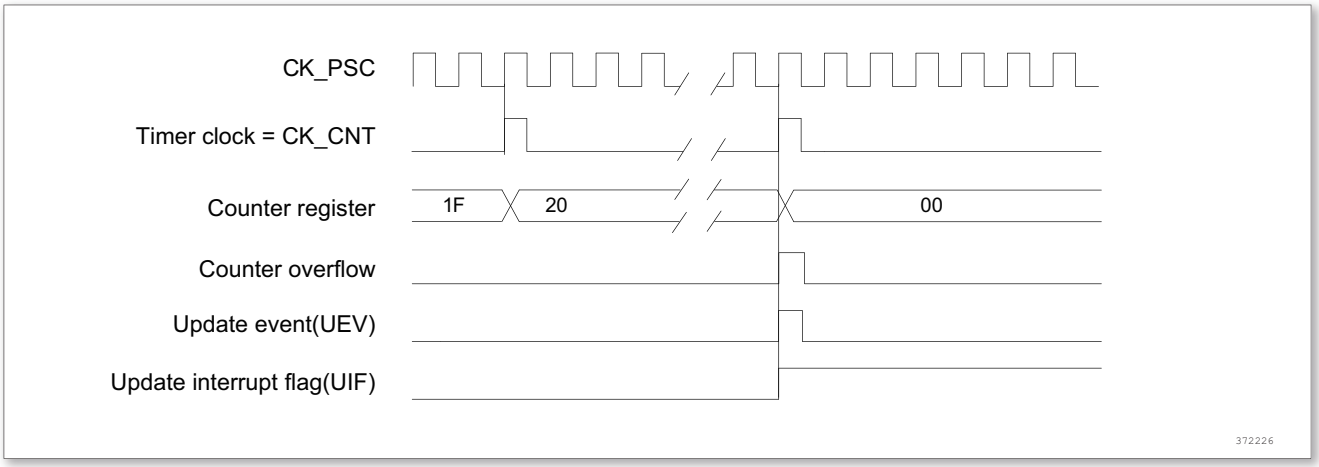

Figure 129. Counter Timing Diagram, Internal Clock Divided by N

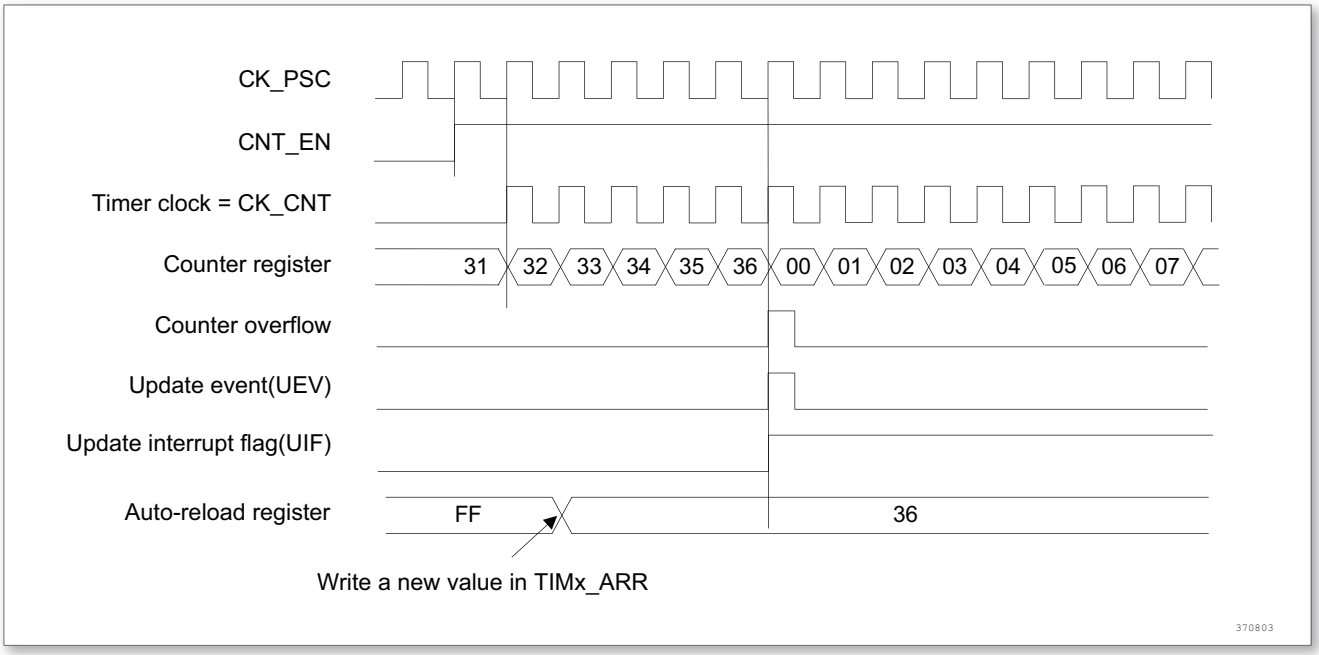

Figure 130. Counter Timing Diagram, Update Event When ARPE = 0 (TiMx_ARR Not Preloaded)

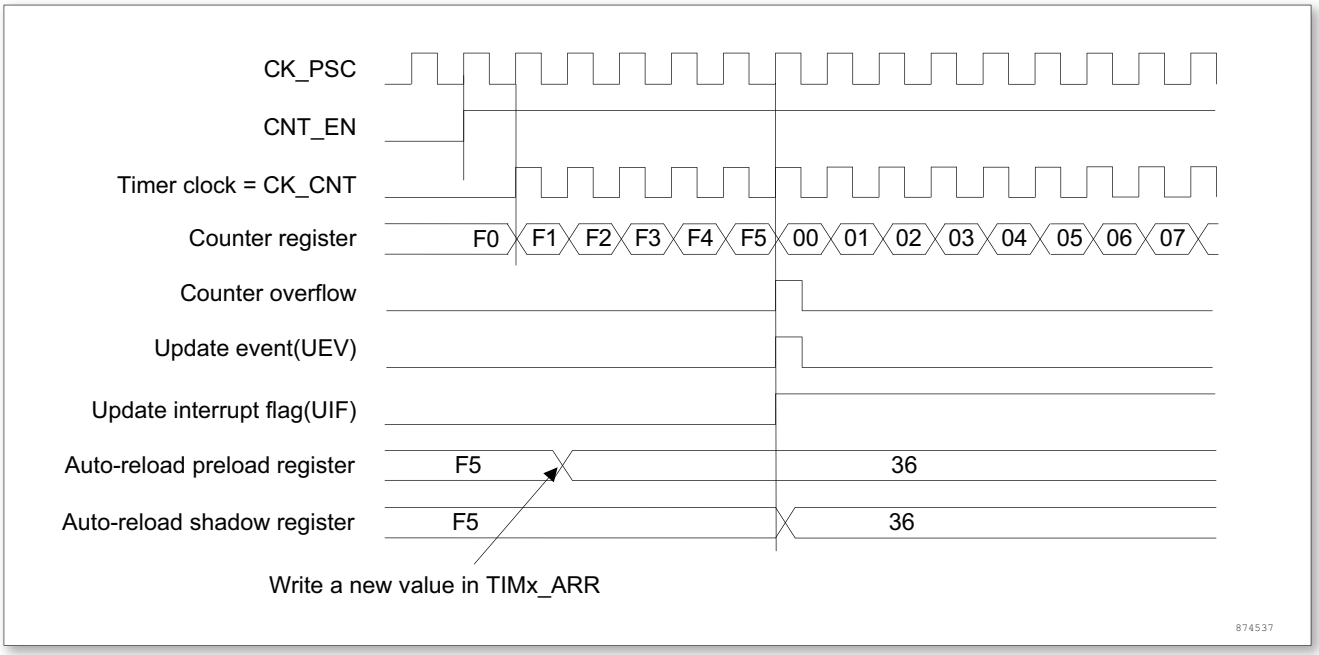

Figure 131. Counter Timing Diagram, Update Event When ARPE = 1 (TiMx_ARR Preloaded)

Downcounting mode

In downcounting mode, the counter counts from the auto-reload value (content of the TIMx_ARR register) down to 0, then restarts from the auto-reload value and generates a counter underflow event.

An Update event can be generated at each counter overflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller).

The UEV update event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter restarts from the current auto-reload value, whereas the counter of the prescaler restarts from 0 (but the prescale rate doesn’t change).

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register).

Note: The auto-reload is updated before the counter is reloaded, so that the next period is the expected one.

The following figures show some examples of the counter behavior for different clock

frequencies when TIMx_ARR = 0x36.

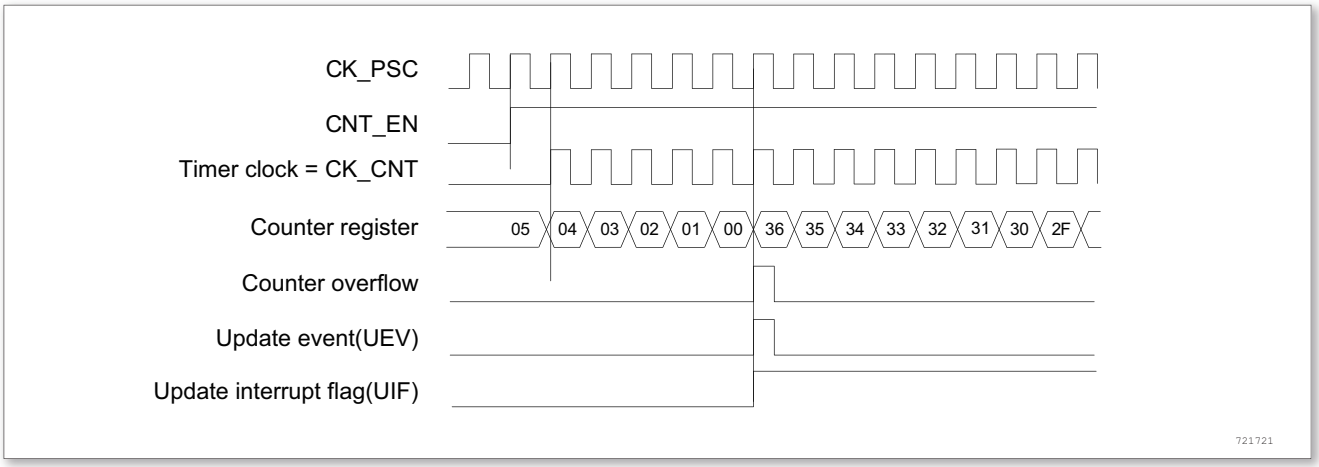

Figure 132. Counter Timing Diagram, Internal Clock Divided by 1

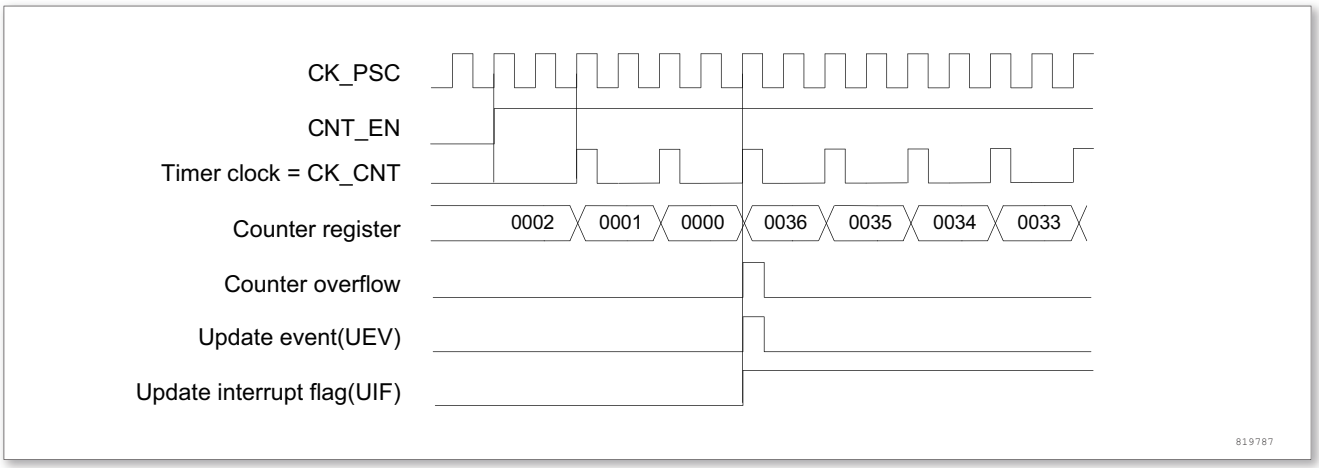

Figure 133. Counter Timing Diagram, Internal Clock Divided by 2

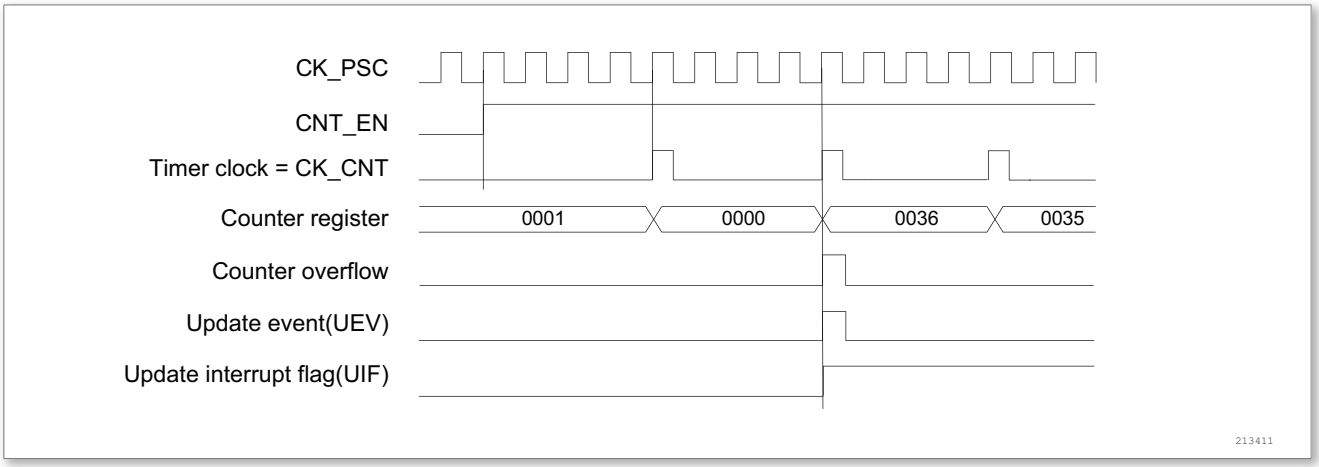

Figure 134. Counter Timing Diagram, Internal Clock Divided by 4

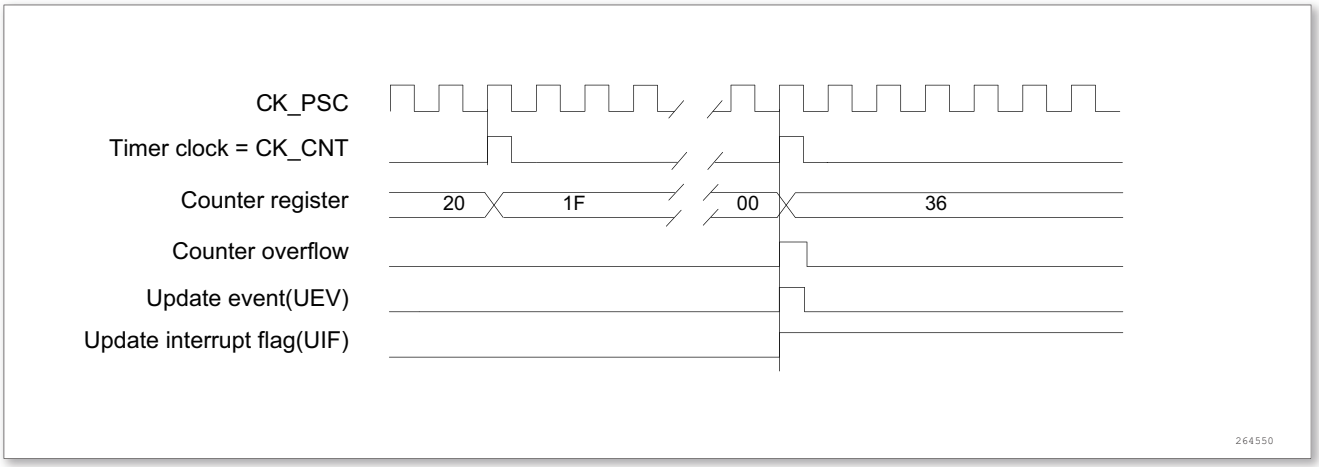

Figure 135. Counter Timing Diagram, Internal Clock Divided by N

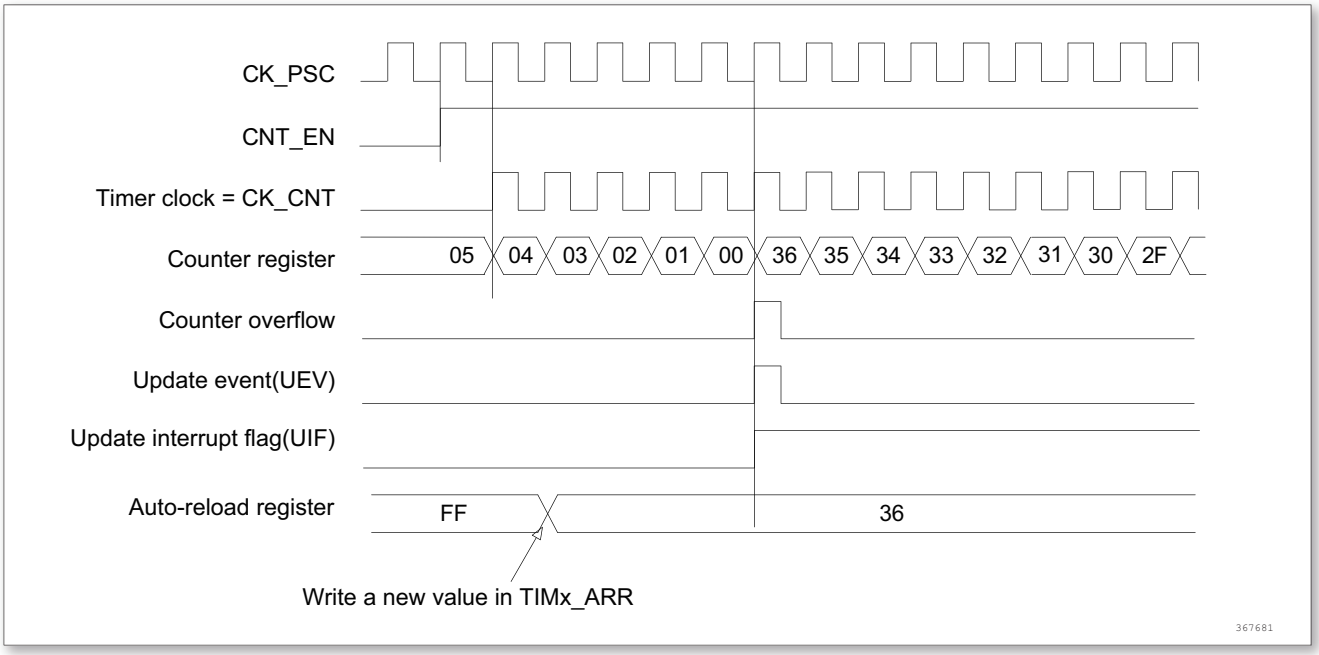

Figure 136. Counter Timing Diagram, Update Event when Repetition Counter is Not Used

Center-aligned mode (Upcounting/Downcounting))

In center-aligned mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register) －1, generates a counter overflow event, then counts from the auto-reload value down to 1 and generates a counter underflow event. Then it restarts counting from 0.

In this mode, the DIR direction bit in the TIMx_CR1 register cannot be written. It is updated by hardware and gives the current direction of the counter.

The update event can be generated at each counter overflow and at each counter underflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) . In this case, the counter restarts counting from 0, so does the counter of the prescaler.

The UEV update event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the

preload registers. Then, no update event occurs until UDIS bit has been written to 0. However, the counter continues counting up and down, based on the current auto-reload value.

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag bit(UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register).

Note: If the update source is a counter overflow, the auto-reload is updated before the counter is reloaded, so that the next period is the expected one (the counter is loaded with the new value).

The following figures show some examples of the counter behavior for different clock frequencies.

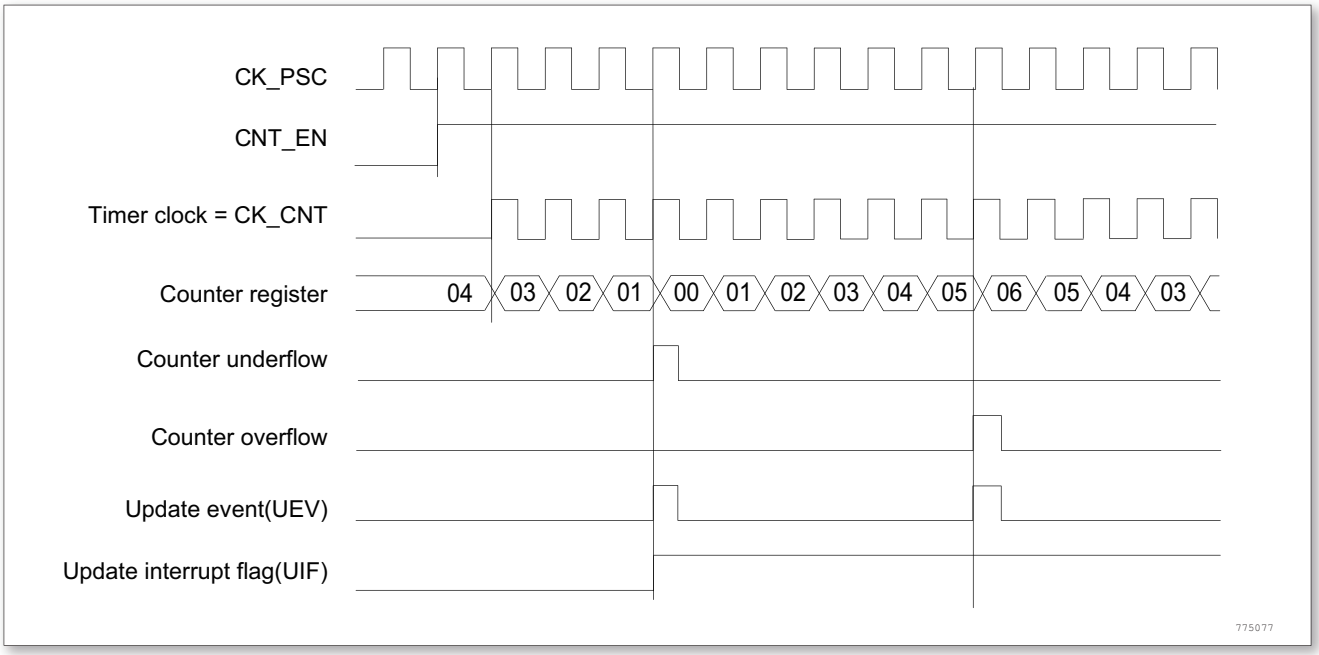

Figure 137. Counter Timing Diagram, Internal Clock Divided by 1, TIMx_ARR = 6

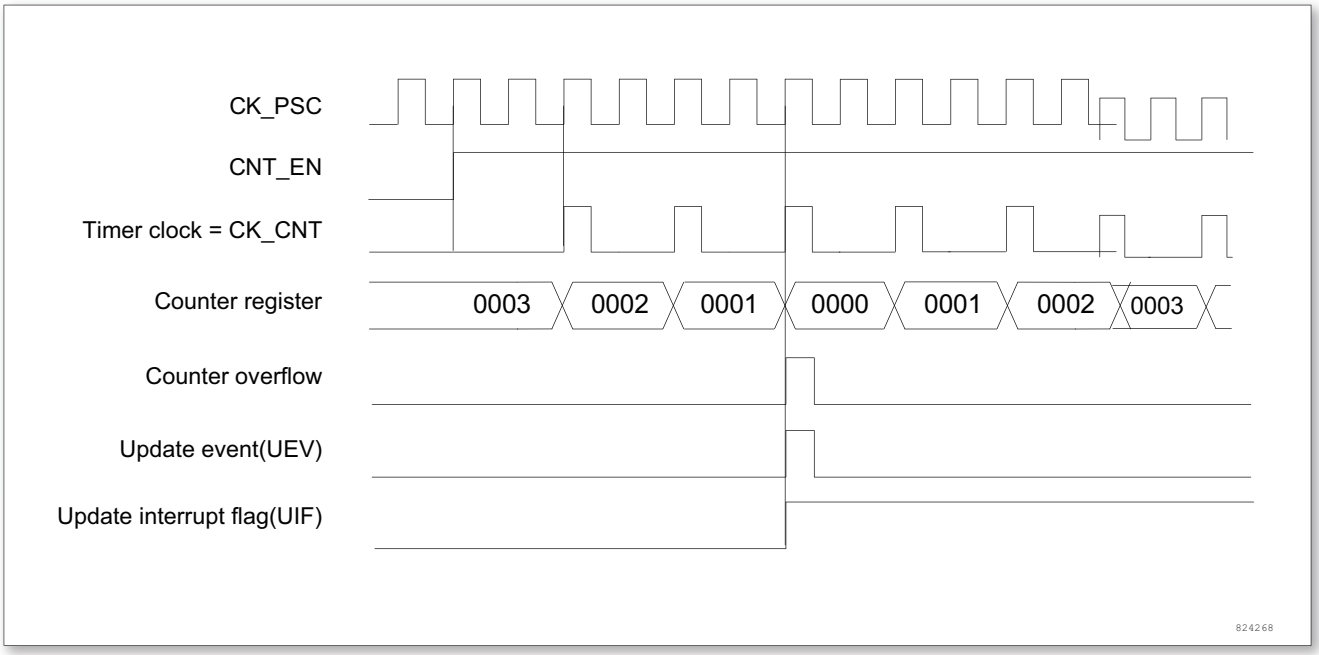

Figure 138. Counter Timing Diagram, Internal Clock Divided by 2

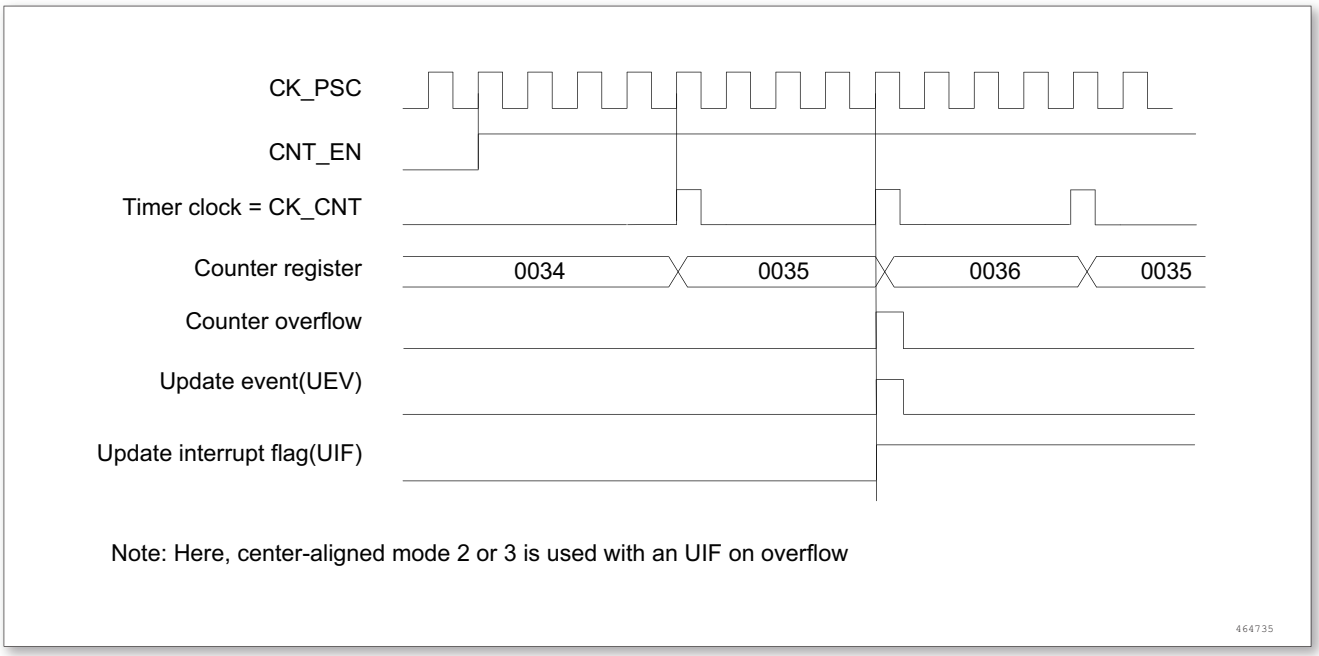

Figure 139. Counter Timing Diagram, Internal Clock Divided by 4, TIMx_ARR = 0x36

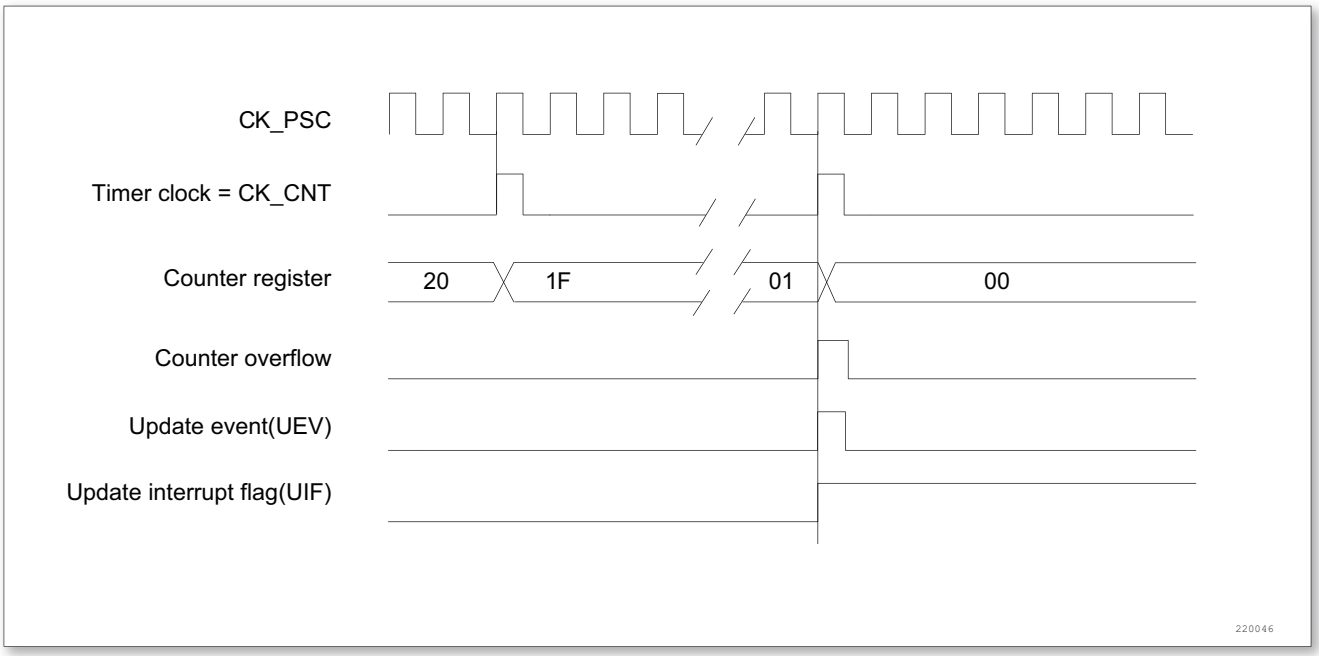

Figure 140. Counter Timing Diagram, Internal Clock Divided by N

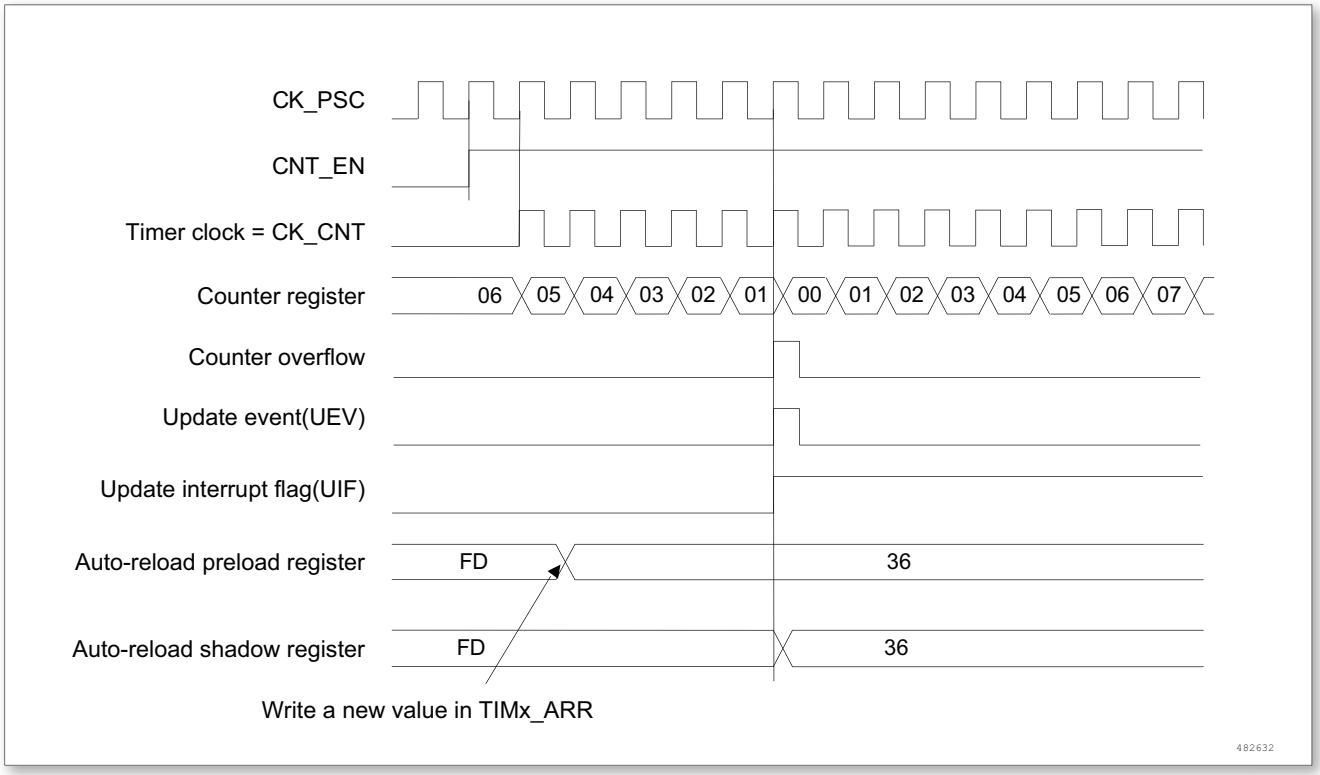

Figure 141. Counter Timing Diagram, Update Event with ARPE = 1(Counter Underflow)

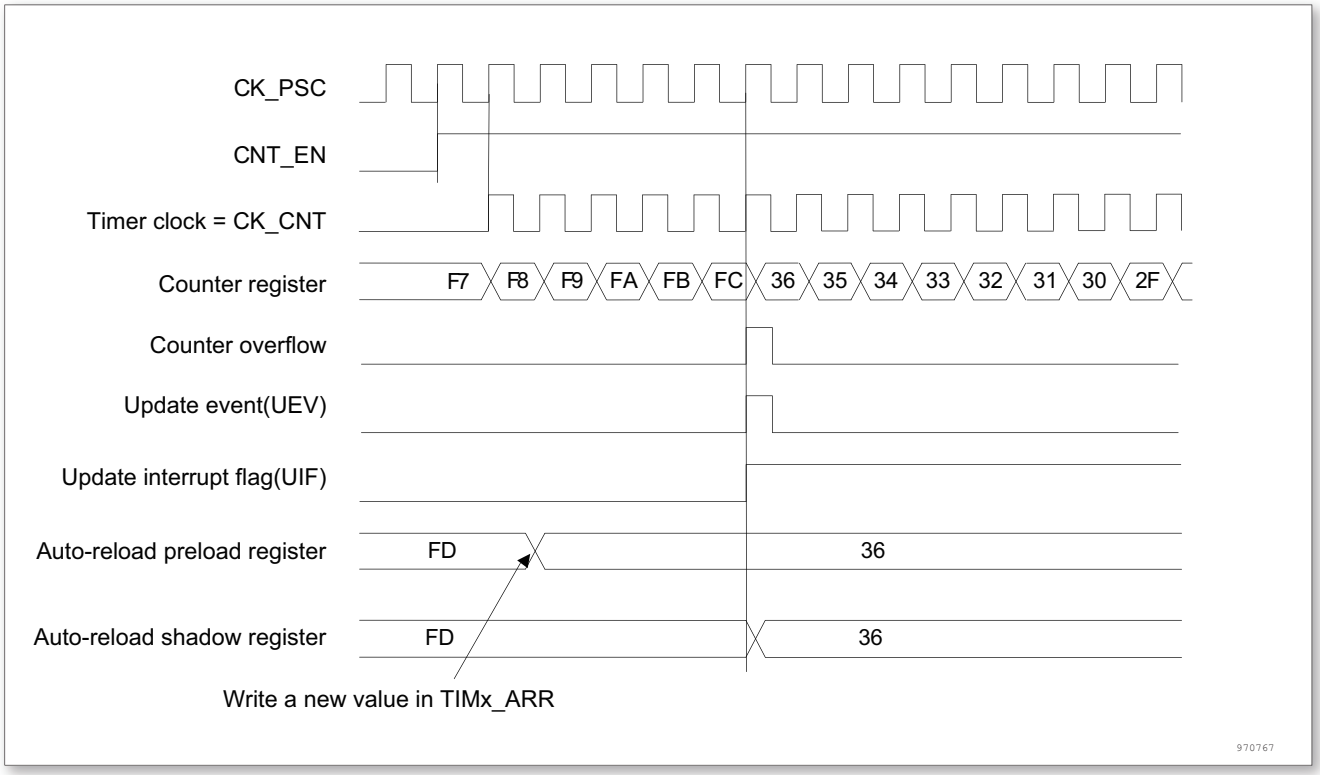

Figure 142. Counter Timing Diagram, Update Event with ARPE = 1(Counter Overflow))

13.3.3 Clock selection

The counter clock can be provided by the following clock sources:

- Internal clock (CK_INT).
- External clock mode1: external input pin (TIx).
- External clock mode2: external trigger input (ETR).
- Internal trigger inputs (ITRx): using one timer as prescaler for another timer, for example, the user can configure Timer 1 to act as a prescaler for Timer 2.

Internal clock (CK_INT)

If the slave mode controller is disabled (SMS=000), then the CEN, DIR (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock CK_INT.

The following figure shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

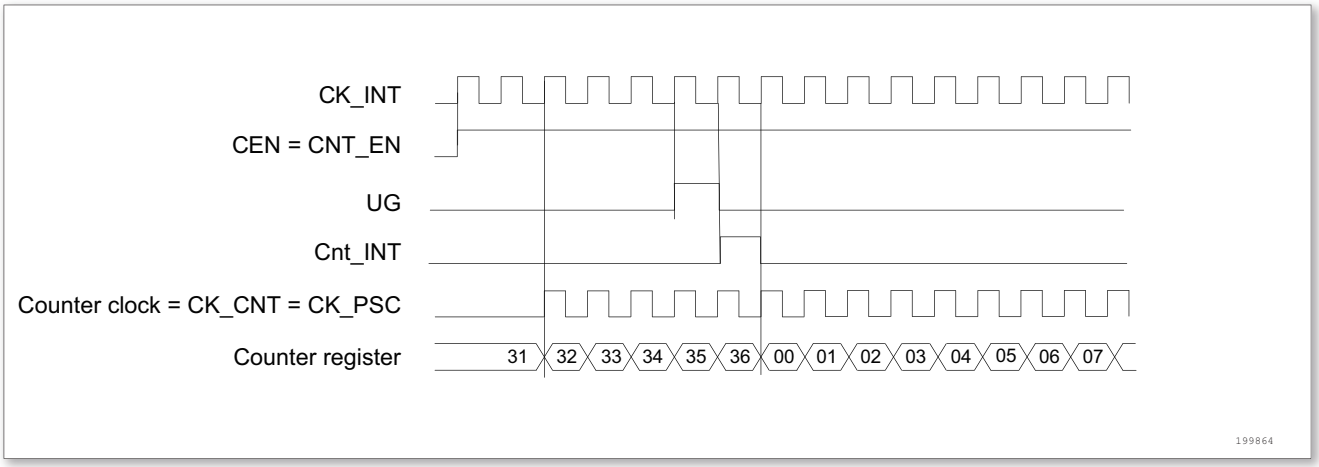

Figure 143. Control Circuit in Normal Mode, Internal Clock Divided By 1

External clock source mode 1

This mode is selected when SMS=111 in the TIMx_SMCR register. The counter can count at each rising or falling edge on a selected input.

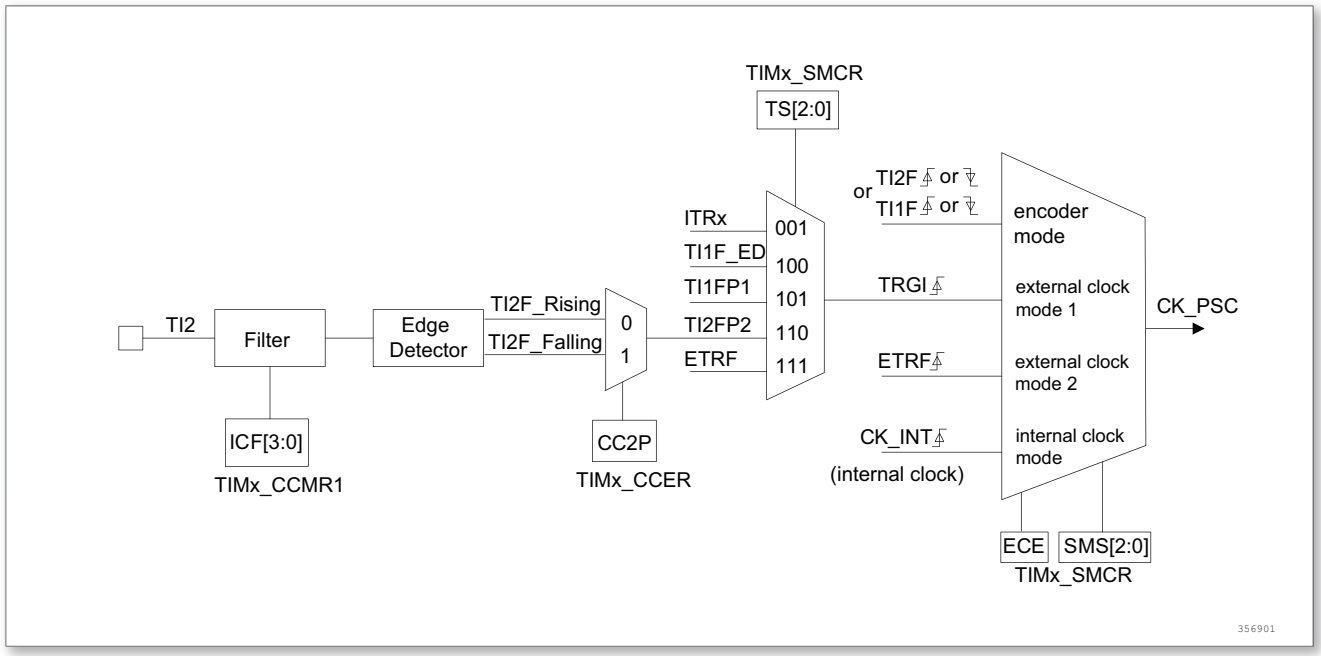

Figure 144. TI2 External Clock Connection Example

For example, to configure the upcounter to count in response to a rising edge on the TI2 input, use the following procedure:

1. Configure channel 2 to detect rising edges on the TI2 input by writing CC2S = ‘01’ in the TIMx_CCMR1 register.
2. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx_CCMR1 register (if no filter is needed, keep IC2F=0000). Note: The capture prescaler is not used for triggering, so there: Tno need to configure it.
3. Select rising edge polarity by writing CC2P=0 in the TIMx_CCER register.
4. Select the timer in external clock mode 1 by writing SMS=111 in the TIMx_SMCR register.

5. Select TI2 as the trigger input source by writing TS=110 in the TIMx_SMCR register.
6. Enable the counter by writing CEN=1 in the TIMx_CR1 register.

When a rising edge occurs on TI2, the counter counts once and the TIF flag is set.

The delay between the rising edge on TI2 and the actual clock of the counter is due to the resynchronization circuit on TI2 input.

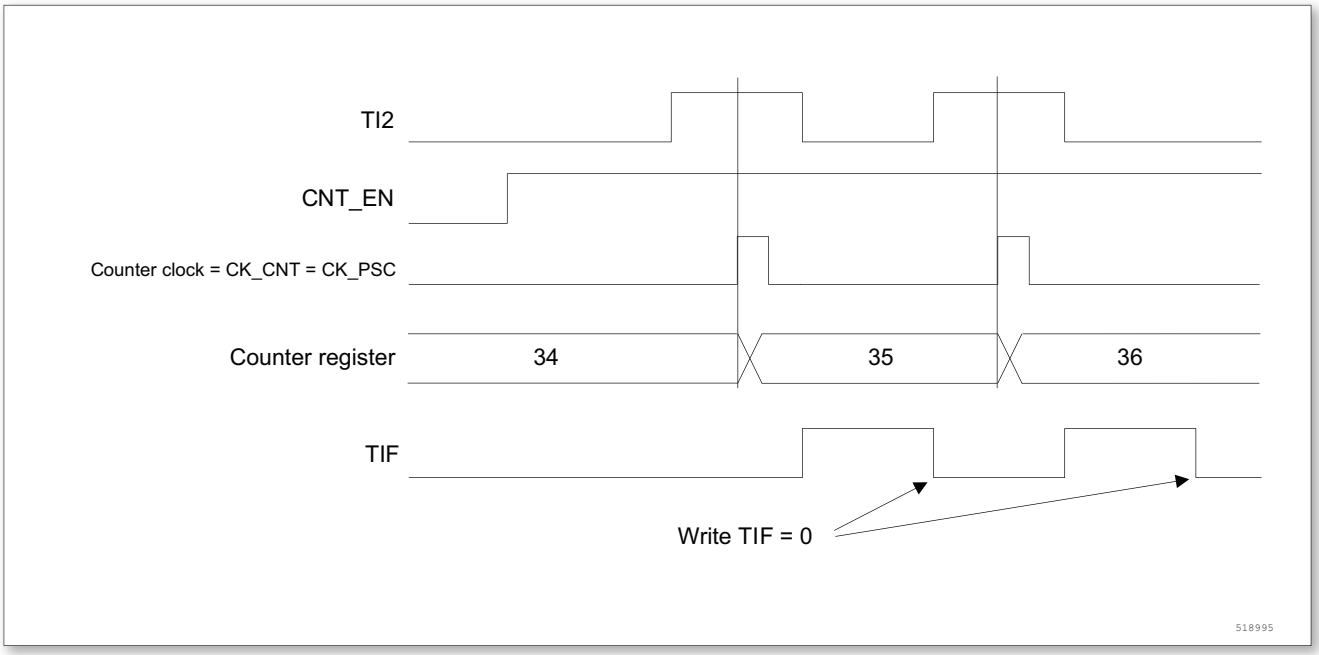

Figure 145. Control Circuit in External Clock Mode 1

External clock source mode 2

This mode is selected by writing ECE = 1 in the TIMx_SMCR register.

The counter can count at each rising or falling edge on the external trigger input ETR.

The following figure gives an overview of the external trigger input block.

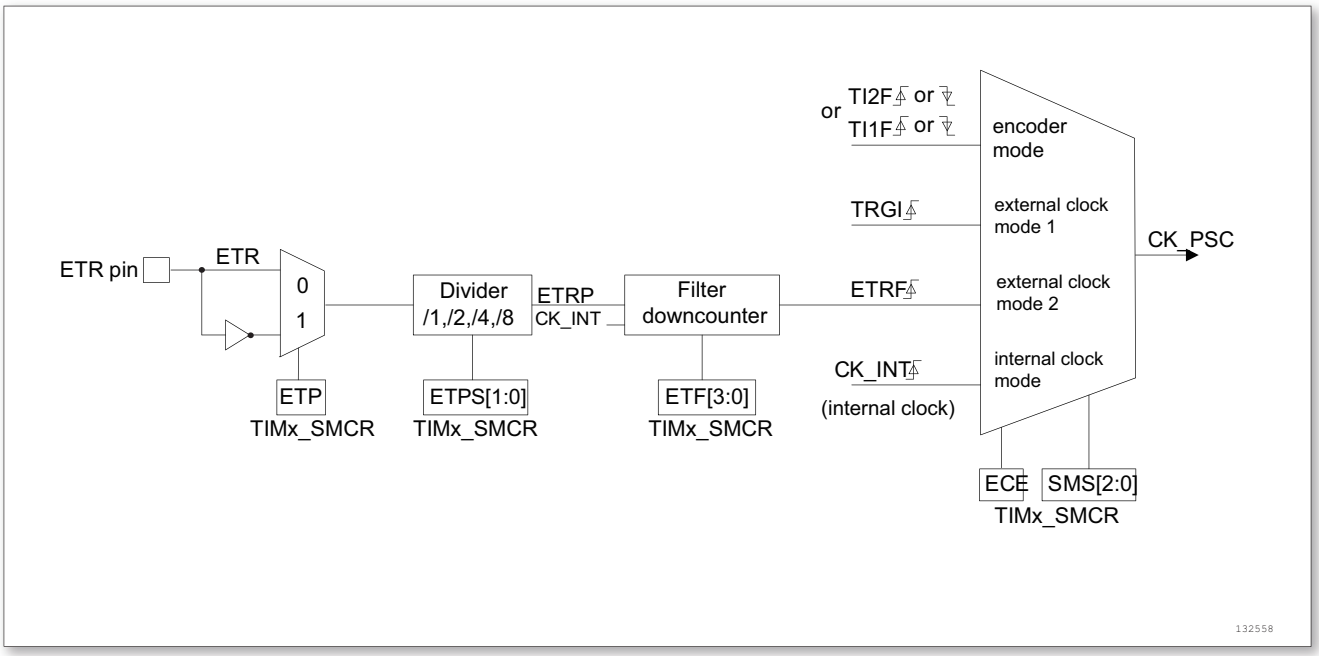

Figure 146. External Trigger Input Block

For example, to configure the upcounter to count once each 2 rising edges on ETR, use the following procedure:

- As no filter is needed in this example, write ETF [3:0]=0000 in the TIMx_SMCR register.
- Set the prescaler by writing ETPS [1:0]=01 in the TIMx_SMCR register.
- Select rising edge detection on the ETR pin by writing ETP=0 in the TIMx_SMCR register.
- Enable external clock mode 2 by writing ECE=1 in the TIMx_SMCR register.
- Enable the counter by writing CEN=1 in the TIMx_CR1 register.

The counter counts once each 2 ETR rising edges.

The delay between the rising edge on ETR and the actual clock of the counter is due to the resynchronization circuit on the ETRP signal.

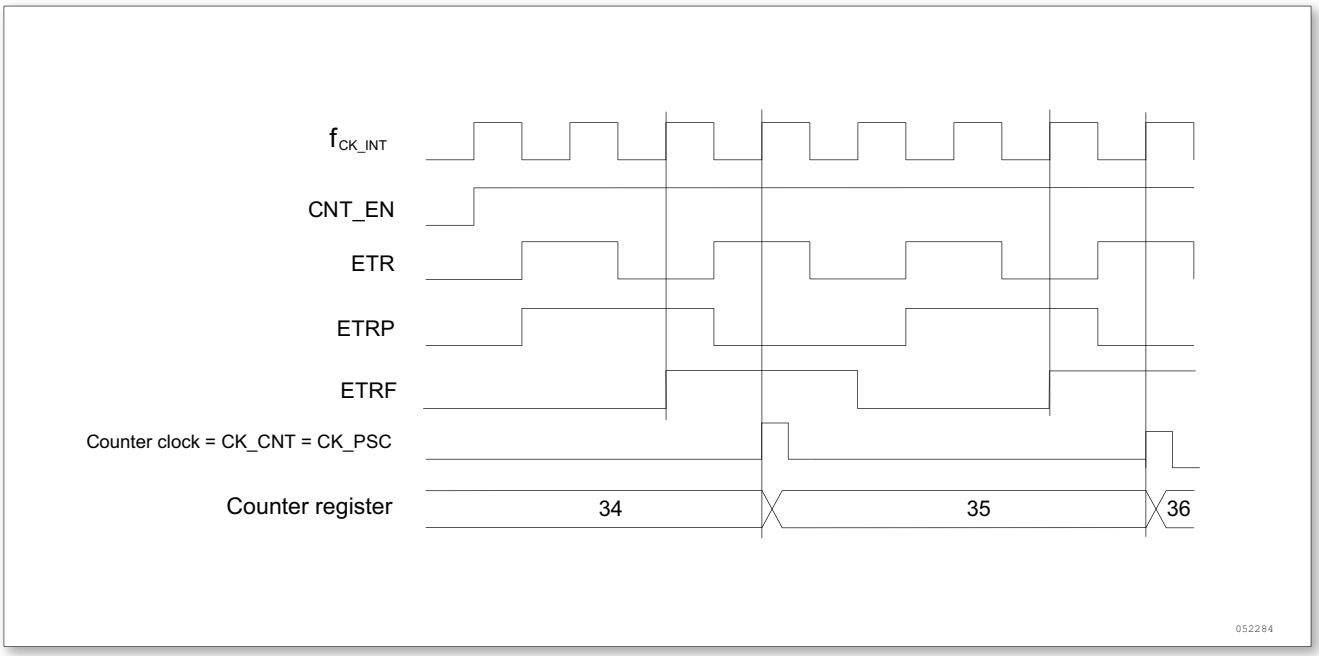

Figure 147. Control Circuit in External Clock Mode 2

13.3.4 Capture/compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), including an input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control).

The following figures show a capture/compare channel. The input stage samples the corresponding TIx input to generate a filtered signal TIxF. Then, an edge detector with polarity selection generates a signal (TIxFPx) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).

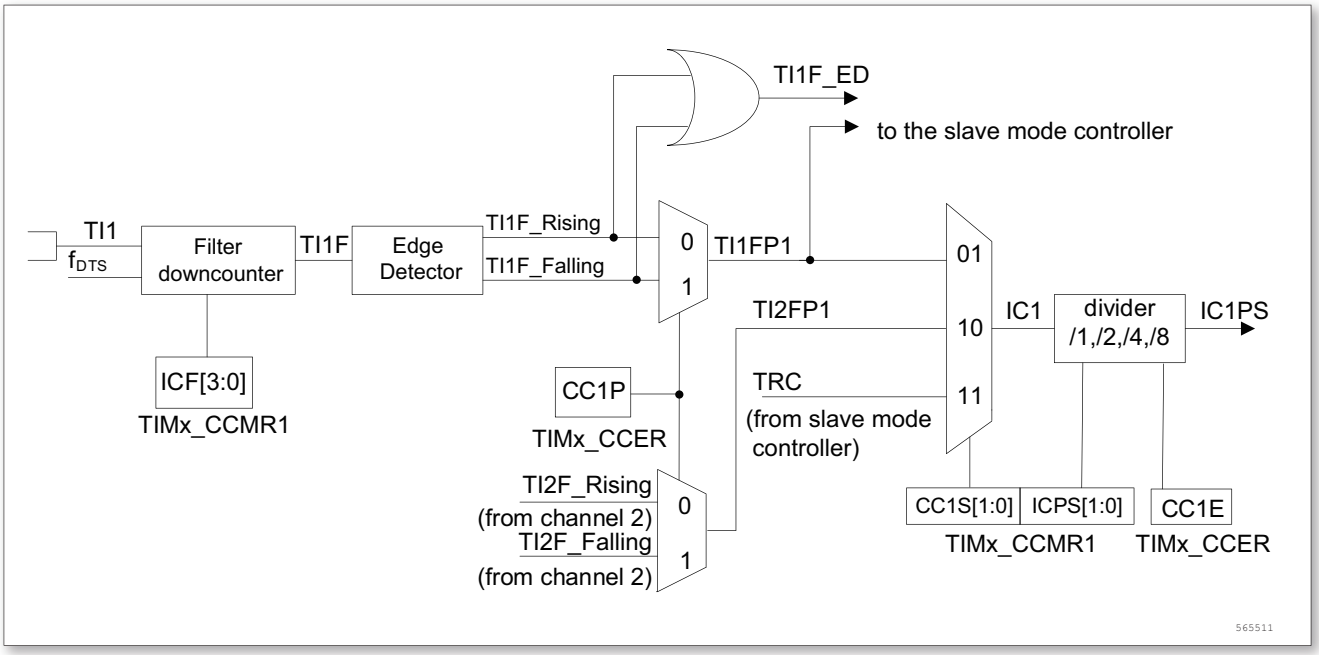

Figure 148. Capture/Compare Channel (Example: Channel 1 Input Stage)

The output stage generates an intermediate waveform which is then used for reference: OCxRef (active high). The polarity acts at the end of the chain.

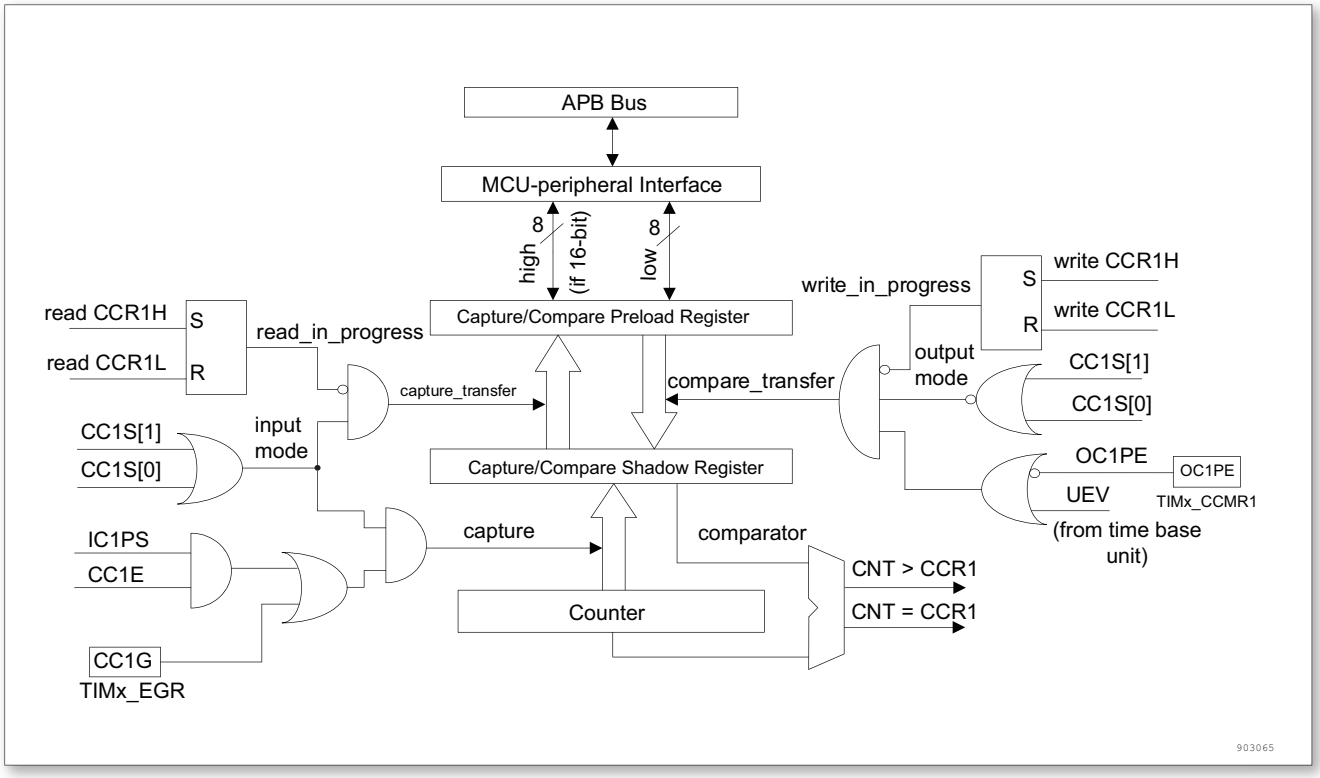

Figure 149. Capture/Compare Channel 1 Main Circuit

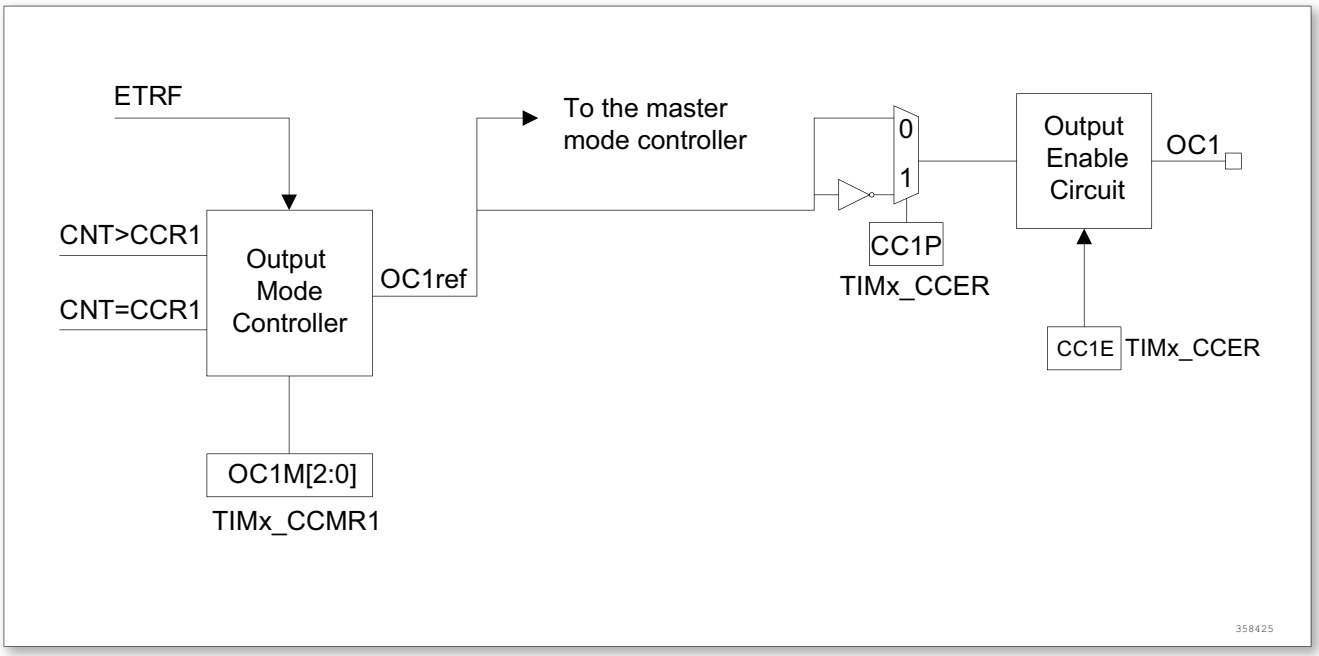

Figure 150. Output Stage of Capture/Compare Channel (Channel 1)

The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register. In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

13.3.5 Input capture mode

In Input capture mode, the Capture/Compare Registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCxIF flag (TIMx_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxOF (TIMx_SR register) is set. CCxIF can be cleared by software by writing it to '0' or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when written to '0'.

The following example shows how to capture the counter value in TIMx_CCR1 when TI1 input rises. To do this, use the following procedure:

- Select the active input: TIMx_CCR1 must be linked to the TI1 input, so write the CC1S bits to 01 in the TIMx_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIMx_CCR1 register becomes read-only.
- Program the needed input filter duration with respect to the signal connected to the timer (by programming ICxF bits in the TIMx_CCMRx register if the input is a TIx input). Let's imagine that, when toggling, the input signal is not stable during at most five internal clock cycles. We must program a filter duration longer than these five clock cycles. We can validate a transition on TI1 when 8 consecutive samples with the new level have been detected (sampled at fDTS frequency). Then write IC1F bits to 0011 in the TIMx_CCMR1 register.

- Select the edge of the active transition on the TI1 channel by writing CC1P bit to 0 in the TIMx_CCER register (rising edge in this case).
- Configure the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to '00' in the TIMx_CCMR1 register).
- Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx_CCER register to '1'.
- If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx_DIER register.

When an input capture occurs:

- TIMx_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- CC1OF is also set to 1.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which could happen after reading the flag and before reading the data.

Note: IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx_EGR register.

13.3.6 PWM input mode

This mode is a particular case of input capture mode. The procedure is the same except:

- Two ICx signals are mapped on the same TIx input.
- These 2 ICx signals are active on edges with opposite polarity.
- One of the two TIxFP signals is selected as trigger input and the slave mode controller is configured in reset mode.

For example, the user can measure the period (in TIMx_CCR1 register) and the duty cycle (in TIMx_CCR2 register) of the PWM applied on TI1 using the following procedure (depending on CK_INT frequency and prescaler value):

- Select the active input for TIMx_CCR1: write the CC1S bits to 01 in the TIMx_CCMR1 register (TI1 selected).
- Select the active polarity for TI1FP1 (used both for capture in TIMx_CCR1 and counter clear): write the CC1P bit to '0' (active on rising edge).
- Select the active input for TIMx_CCR2: write the CC2S bits to 10 in the TIMx_CCMR1 register (TI1 selected).
- Select the active polarity for TI1FP2 (used for capture in TIMx_CCR2): write the CC2P bit to '1' (active on falling edge).
- Select the valid trigger input: write the TS bits to 101 in the TIMx_SMCR register (TI1FP1 selected).
- Configure the slave mode controller in reset mode: write the SMS bits to 100 in the

TIMx_SMCR register.

- Enable the captures: write the CC1E and CC2E bits to ‘1’ in the TIMx_CCER register.

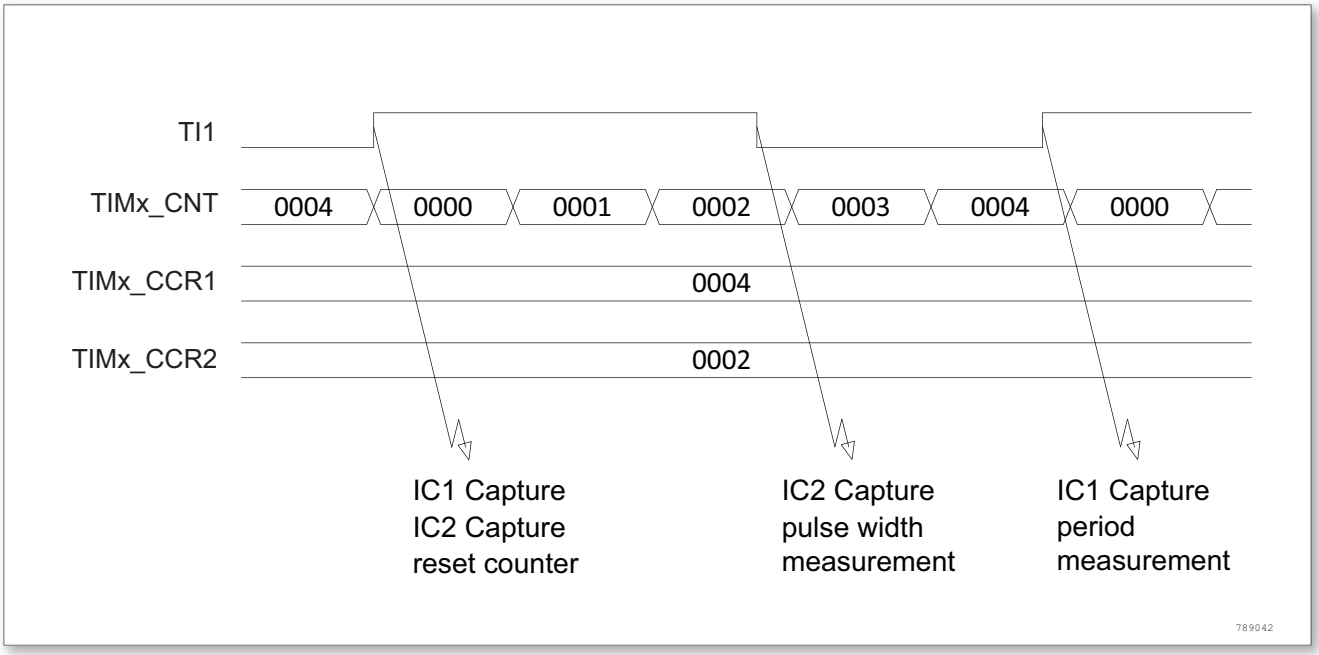

Figure 151. Output Stage of Capture/Compare Channel (Channel 1)

The PWM input mode can be used only with the TIMx_CH1/TIMx_CH2 signals due to the fact that only TI1FP1 and TI2FP2 are connected to the slave mode.

13.3.7 Forced output mode

In output mode (CCxS bits = 00 in the TIMx_CCMRx register), each output compare signal (OCxREF and then OCx/OCxN) can be forced to active or inactive level directly by software, being independent of any comparison between the output compare register and the counter.

To force an output compare signal (OCXREF/OCx) to its active level, the user just needs to write 101 in the OCxM bits in the corresponding TIMx_CCMRx register. Thus OCXREF is forced high (OCxREF is always active high) and OCx get opposite value to CCxP polarity bit.

For example: CCxP=0 (OCx active high) => OCx is forced to high level.

The OCxREF signal can be forced low by writing the OCxM bits to 100 in the TIMx_CCMRx register.

Anyway, in this mode, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the output compare mode section below.

13.3.8 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output

compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP bit in the TIMx_CCER register). The output pin can keep its level (OCXM=000), be set active (OCxM=001), be set inactive (OCxM=010) or can toggle (OCxM=011) on match.
- Sets a flag bit in the interrupt status register (CCxIF bit in the TIMx_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCXIE bit in the TIMx_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx_DIER register, CCDS bit in the TIMx_CR2 register for the DMA request selection).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

In output compare mode, the update event UEV has no effect on OCxREF and OCx output.

The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One Pulse mode)

Procedure:

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
3. Set the CCxIE and/or CCxDE bits if an interrupt and/or a DMA request is to be generated.
4. Select the output mode. For example, the user must write OCxM=011, OCxPE=0, CCxP=0 and CCxE=1 to toggle OCx output pin when CNT matches CCRx, CCRx preload is not used, OCx is enabled and active high.
5. Enable the counter by setting the CEN bit in the TIMx_CR1 register.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE=’0’, else TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in the following figure.

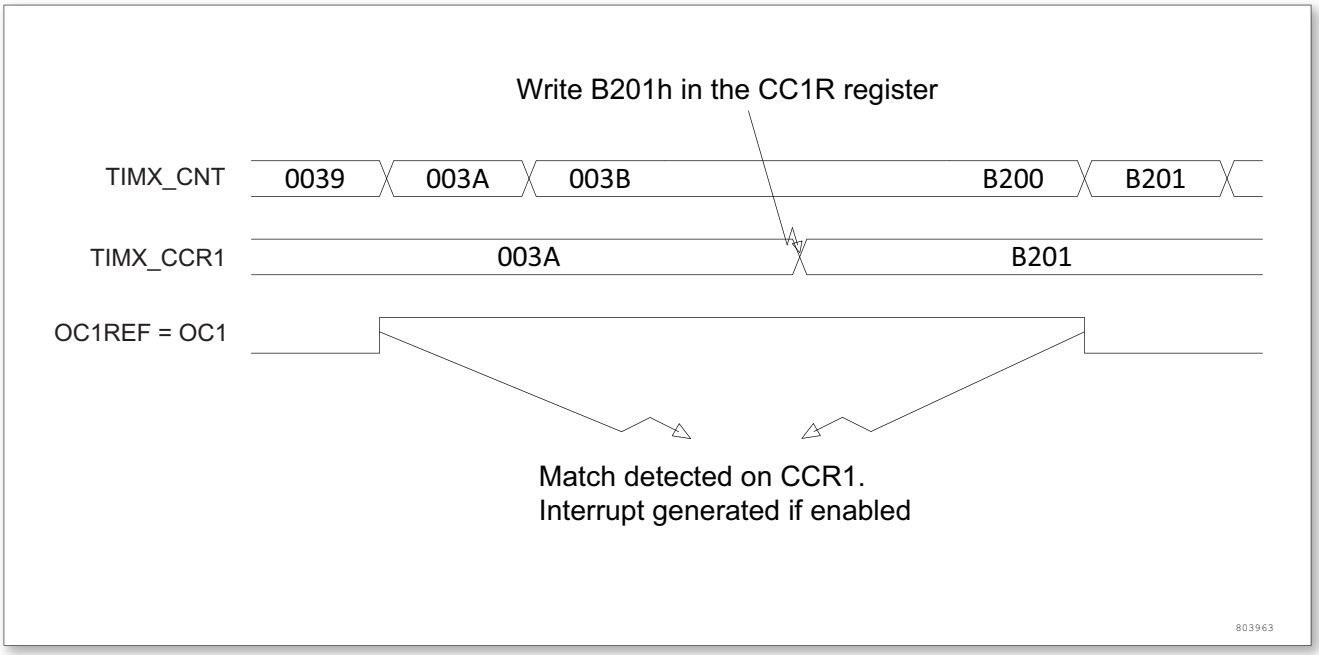

Figure 152. Output Compare Mode (Toggle OC1)

13.3.9 PWM mode

Pulse Width Modulation mode allows generating a signal with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per OCx output) by writing ‘110’ (PWM mode 1) or ‘111’ (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, the user must initialize all the registers by setting the UG bit in the TIMx_EGR register.

OCx polarity is software programmable using the CCxP bit in the TIMx_CCER register. It can be programmed as active high or active low. OCx output is enabled by the CCxE bit in the TIMx_CCER register. Refer to the TIMx_CCERx register description for more details.

In PWM mode (1 or 2), TIMx_CNT and TIM1_CCRx are always compared to determine whether TIM1_CCRx≤TIM1_CNT or TIM1_CNT≤TIM1_CCRx (depending on the direction of the counter). However, to comply with the OCREF_CLR (OCxREF can be cleared by an external event through the ETR signal until the next PWM period), the OCxREF signal is asserted only:

- When the result of the comparison changes
- When the output compare mode (OCxM bits in TIMx_CCMRx register) switches from the period), the OC enabled by the CCxE bit in the TIMx_CCER register. Refer to the

TIMx_CCERx register

This forces the PWM by software while the timer is running. The timer is able to generate PWM in edge-aligned mode or center-aligned mode depending on the CMS bits in the TIMx_CR1 register.

PWM edge-aligned mode

Upcounting configuration

Upcounting is active when the DIR bit in the TIMx_CR1 register is low.

In the following example, we consider PWM mode 1. The reference PWM signal OCxREF is high as long as TIMx_CNT < TIMx_CCRx, otherwise it becomes low. If the compare value in TIMx_CCRx is greater than the auto-reload value (in TIMx_ARR) then OCxREF is held at ‘1’. If the compare value is 0 then OCxRef is held at ‘0’. Figure 61 shows some edge-aligned PWM waveforms in an example where TIMx_ARR=8.

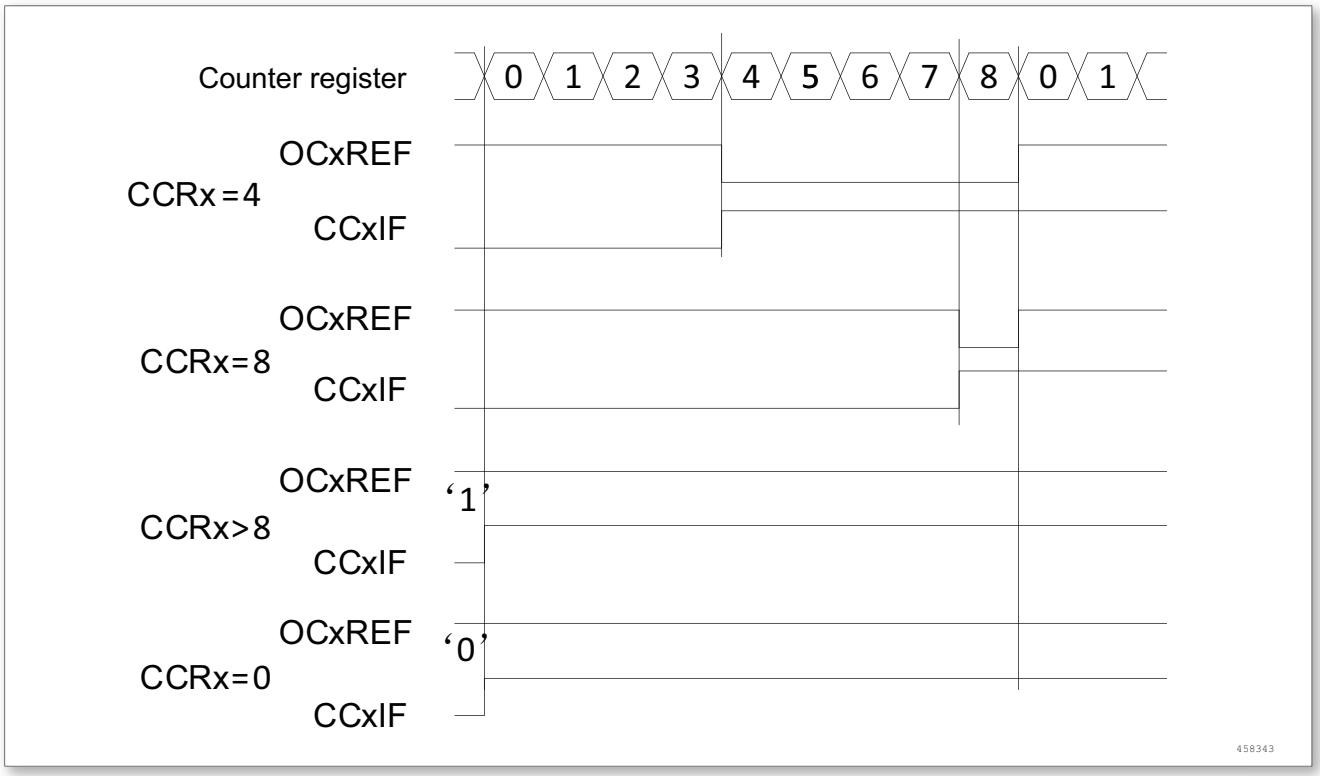

Figure 153. Edge-aligned PWM Waveforms (ARR = 8)

Downcounting configuration

Downcounting is active when DIR bit in TIMx_CR1 register is high.

In PWM mode 1, the reference signal OCxRef is low as long as TIMx_CNT > TIMx_CCRx, otherwise it becomes high. If the compare value in TIMx_CCRx is greater than the auto-reload value in TIMx_ARR, then OCxREF is held at ‘1’. 0% PWM is not possible in this mode.

PWM center-aligned mode

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are different from ‘00’ (all the remaining configurations having the same effect on the OCxRef/OCx signals).

The compare flag is set when the counter counts up, when it counts down or when it counts up and down depending on the CMS bits configuration. The direction bit (DIR) in the TIMx_CR1 register is updated by hardware and must not be changed by software. Refer to section 11.3.2 Center-aligned Mode.

The following figure shows some center-aligned PWM waveforms in an example, where:

- TIMx_ARR = 8
- PWM mode 1
- The flag is set when the counter counts down corresponding to the center-aligned mode 1 selected for CMS=01 in TIMx_CR1 register.

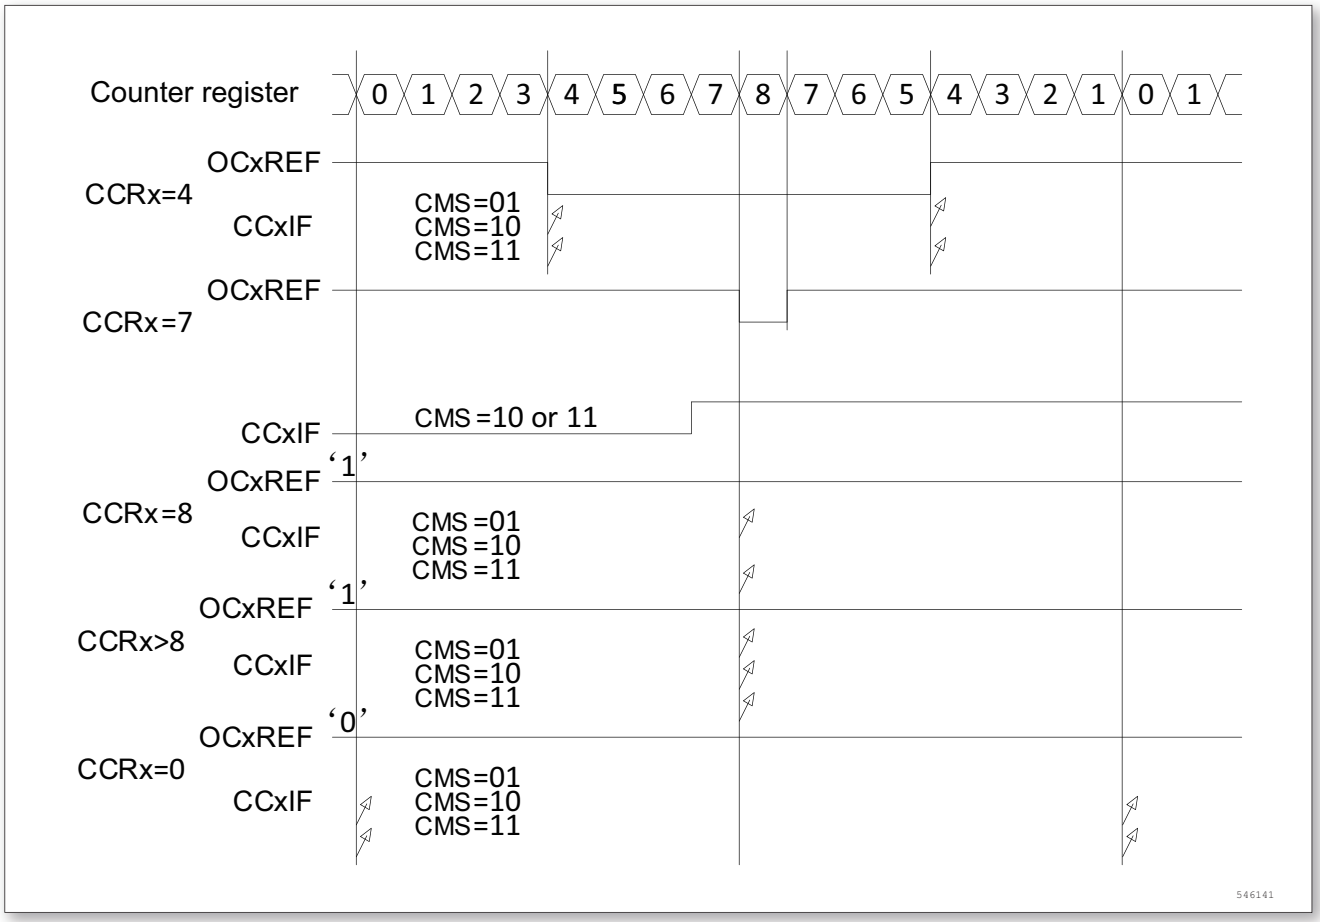

Figure 154. Center-aligned PWM Waveforms (ARR = 8)

Hints in center-aligned mode:

- When starting in center-aligned mode, the current up-down configuration is used. It means that the counter counts up or down depending on the value written in the DIR bit in the TIMx_CR1 register. Moreover, the DIR and CMS bits must not be changed at the same time by the software.
- Writing to the counter while running in center-aligned mode is not recommended as it can lead to unexpected results. In particular:
  - The direction is not updated if the user writes a value in the counter greater than the auto-reload value (TIMx_CNT>TIMx_ARR). For example, if the counter was counting up, it will continue to count up.

  - The direction is updated if the user writes 0 or write the TIMx_ARR value in the counter but no Update Event UEV is generated
- The safest way to use center-aligned mode is to generate an update by software (setting the UG bit in the TIMx_EGR register) just before starting the counter and not to write the counter while it is running.

13.3.10 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. Select One-pulse mode by setting the OPM bit in the TIMx_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- In upcounting: CNT < CCRx ≤ ARR (in particular, 0 < CCRx)
- In downcounting: CNT > CCRx

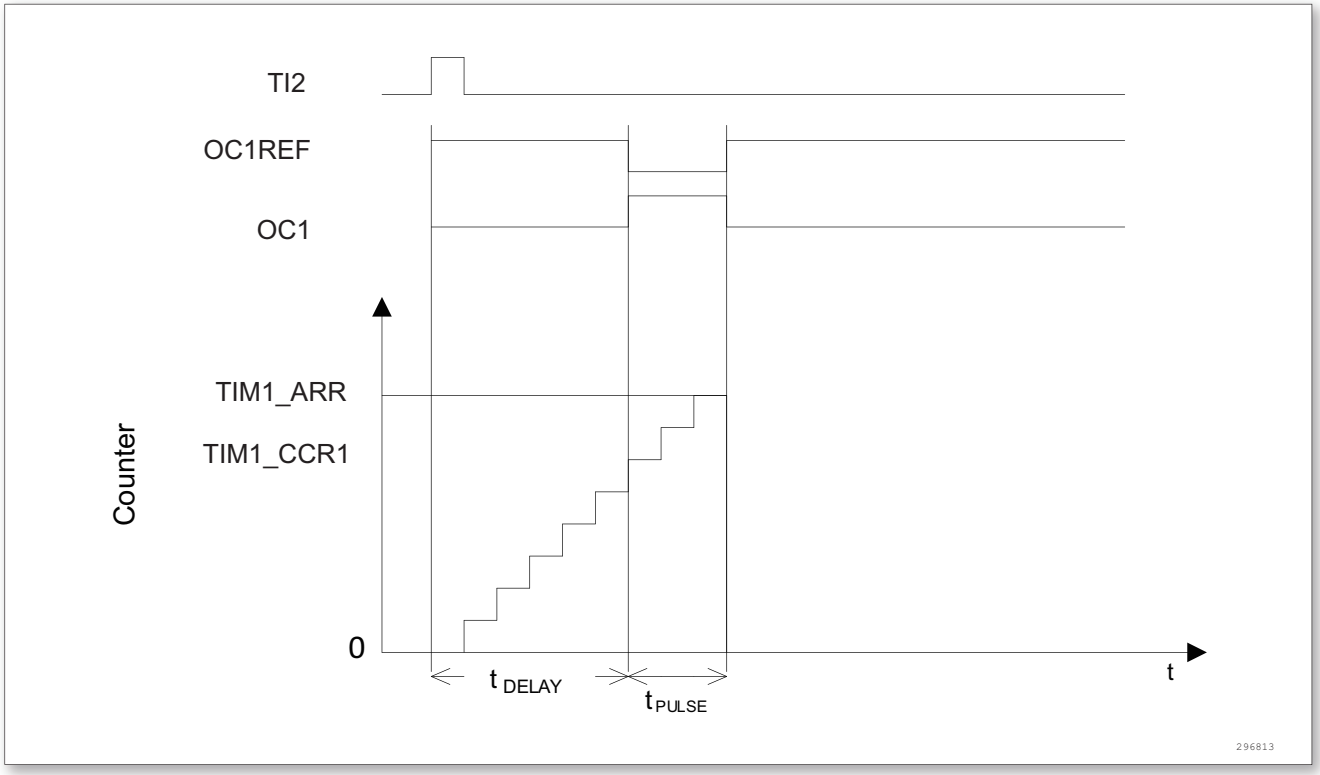

Figure 155. Example of One Pulse Mode

For example the user may want to generate a positive pulse on OC1 with a length of t_{PULSE} and after a delay of t_{DELAY} as soon as a positive edge is detected on the TI2 input pin.

Let’s use TI2FP2 as trigger 1:

- Map TI2FP2 to TI2 by writing CC2S = ’01’ in the TIMx_CCMR1 register.
- TI2FP2 must detect a rising edge, write CC2P = ’0’ in the TIMx_CCER register.
- Configure TI2FP2 as trigger for the slave mode controller (TRGI) by writing TS = ’110’ in the TIMx_SMCR register.
- TI2FP2 is used to start the counter by writing SMS to ’110’ in the TIMx_SMCR register (trigger mode).

The OPM waveform is defined by the value written in the compare registers (taking into account the clock frequency and the counter prescaler)

- The t_{DELAY} is defined by the value written in the TIMx_CCR1 register.
- The t_{PULSE} is defined by the difference between the auto-reload value and the compare value (TIMx_ARR - TIMx_CCR1).
- Let us say the user wants to build a waveform with a transition from ’0’ to ’1’ when a compare match occurs and a transition from ‘1’ to ‘0’ when the counter reaches the auto-reload value. To do this, enable PWM mode 2 by writing OC1M=111 in the TIMx_CCMR1 register. The user can optionally enable the preload registers by writing OC1PE=’1’ in the TIMx_CCMR1 register and ARPE in the TIMx_CR1 register. In this case the compare value must be written in the TIMx_CCR1 register, the auto-reload value in the TIMx_ARR register, generate an update by setting the UG bit and wait for external trigger event on TI2. CC1P is written to ‘0’ in this example.

In our example, the DIR and CMS bits in the TIMx_CR1 register should be low.

The user only wants one pulse (Single mode), so ’1’ must be written in the OPM bit in the TIMx_CR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0).

Particular case: OCx fast enable

In One-pulse mode, the edge detection on TIx input sets the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay t_{DELAY} min we can get.

If the user wants to output a waveform with the minimum delay, the OCxFE bit in the TIMx_CCMRx register must be set. Then OCxRef (and OCx) are forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

13.3.11 Clearing the OCxREF signal on an external event

The OCxREF signal for a given channel can be driven Low by applying a High level to the ETRF input (OCxCE enable bit of the corresponding TIMx_CCMRx register set to ‘1’). The OCxREF signal remains Low until the next update event, UEV, occurs.

This function can only be used in output compare and PWM modes, and does not work in forced mode.

For example, the OCxREF signal can be connected to the output of a comparator to be

used for current handling. In this case, the ETR must be configured as follow:

- The External Trigger Prescaler should be kept off: bits ETPS[1:0] of the TIMx_SMCR register set to ‘00’.
- The external clock mode 2 must be disabled: bit ECE of the TIMx_SMCR register set to ‘0’.
- The External Trigger Polarity (ETP) and the External Trigger Filter (ETF) can be configured according to the user needs.

The following Figure shows the behavior of the OCxREF signal when the ETRF Input becomes High, for both values of the enable bit OCxCE. In this example, the timer TIMx is programmed in PWM mode.

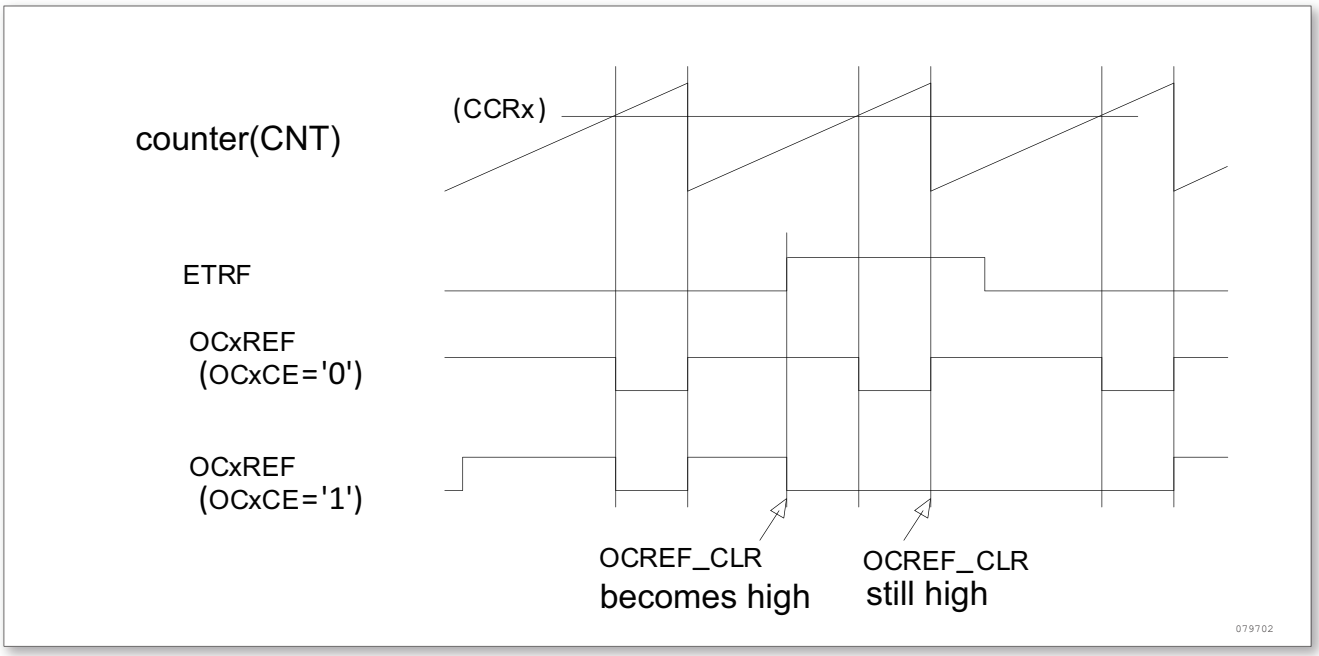

Figure 156. Clearing TIMx OCxREF

13.3.12 Encoder interface mode

To select Encoder Interface mode write SMS=‘001’ in the TIMx_SMCR register if the counter is counting on TI2 edges only, SMS=’010’ if it is counting on TI1 edges only and SMS=’011’ if it is counting on both TI1 and TI2 edges.

Select the TI1 and TI2 polarity by programming the CC1P and CC2P bits in the TIMx_CCER register. When needed, the user can program the input filter as well.

The two inputs TI1 and TI2 are used to interface to an incremental encoder. Assuming that the counter is enabled (CEN bit in TIMx_CR1 register written to ‘1) in the following table, it is clocked by each valid transition on TI1FP1 or TI2FP2 (TI1 and TI2 after input filter and polarity selection, TI1FP1=TI1 if not filtered and not inverted, TI2FP2=TI2 if not filtered and not inverted). The sequence of transitions of the two inputs is evaluated and generates count pulses as well as the direction signal. Depending on the sequence the counter counts up or down, the DIR bit in the TIMx_CR1 register is modified by hardware accordingly. The DIR bit is calculated at each transition on any input (TI1 or TI2), whatever the counter is counting on TI1 only, TI2 only or both TI1 and TI2.

Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the auto-reload value in the TIMx_ARR register (0 to ARR or ARR down to 0 depending on the direction). So user must configure TIMx_ARR before starting. In the same way, the capture, compare, prescaler, trigger output features continue to work as normal.

In this mode, the counter is modified automatically following the speed and the direction of the incremental encoder and its content, therefore, always represents the encoder’s position. The count direction corresponds to the rotation direction of the connected sensor. The following table summarizes the possible combinations, assuming TI1 and TI2 do not switch at the same time.

Table 45. Counting Direction Versus Encoder Signals

Active edge	Level on opposite signal (TI1FP1 for TI2, TI2FP2 for TI1)	TI1FP1 signal		TI1FP2 signal	
		Rising	Falling	Rising	Falling
Counting on TI1 only	High	Down	Up	No Count	No Count
	Low	Up	Down	No Count	No Count
Counting on TI2 only	High	No Count	No Count	Up	Down
	Low	No Count	No Count	Down	Up
Counting on TI1 and TI2	High	Down	Up	Up	Down
	Low	Up	Down	Down	Up

An external incremental encoder can be connected directly to the MCU without external interface logic. However, comparators are normally be used to convert the encoder’s differential outputs to digital signals. This greatly increases noise immunity. The third encoder output which indicate the mechanical zero position, may be connected to an external interrupt input and trigger a counter reset.

The following figure gives an example of counter operation, showing count signal generation and direction control. It also shows how input jitter is compensated where both edges are selected. This might occur if the sensor is positioned near to one of the switching points.

For this example, we assume that the configuration is the following:

- CC1S=’01’ (TIMx_CCMR1 register, TI1FP1 mapped on TI1).
- CC2S=’01’ (TIMx_CCMR2 register, TI1FP2 mapped on TI2).
- CC1P=’0’, (TIMx_CCER register, IC1FP1 non-inverted, IC1FP1=TI1).
- C2P= ’0’ (TIMx_CCER register, IC2FP2 non-inverted, IC2FP2=TI2).
- SMS= ’011’ (TIMx_SMCR register, all inputs are active on both rising and falling edges).
- CEN= ’1’ (TIMx_CR1 register, Counter enabled).

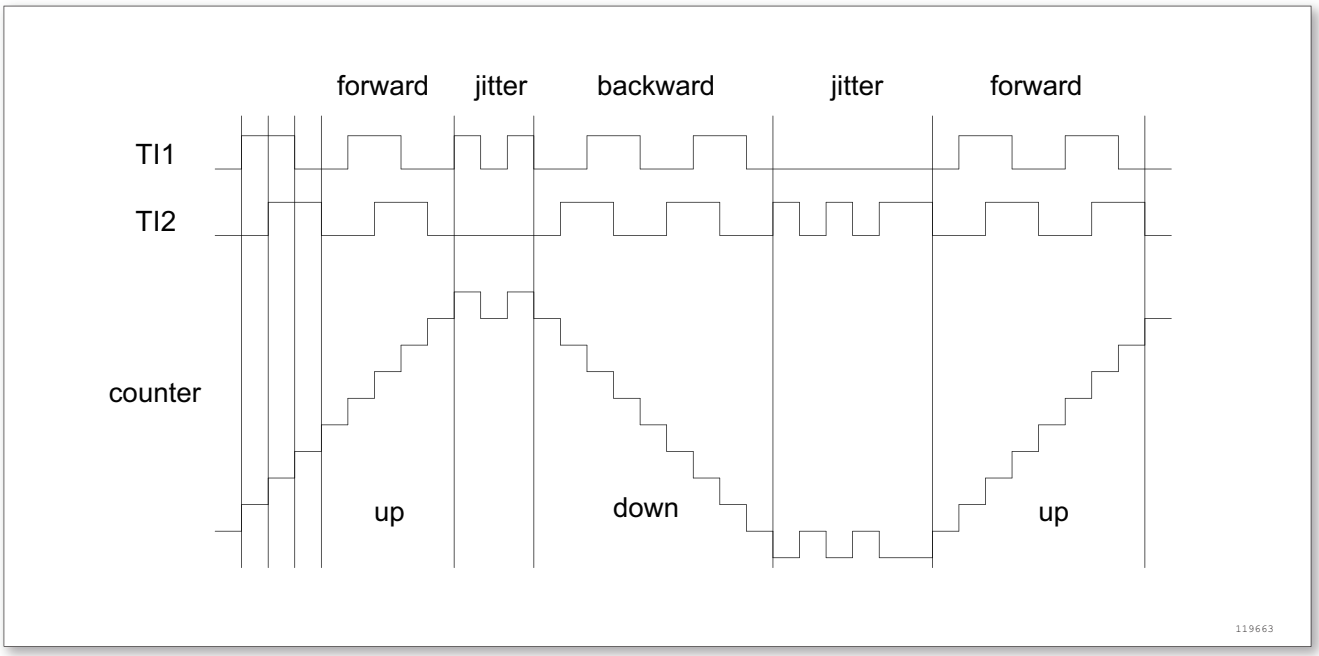

Figure 157. Example of Counter Operation in Encoder Mode

The following figure gives an example of counter behavior when IC1FP1 polarity is inverted (same configuration as above except CC1P=1).

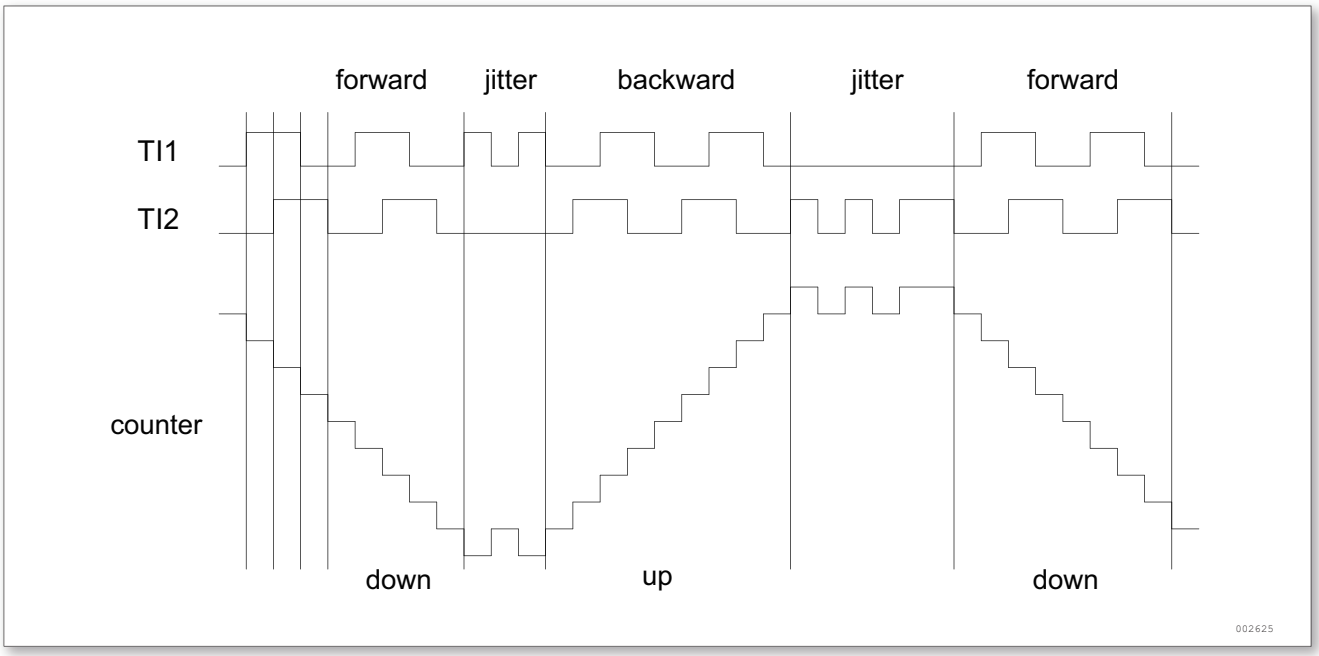

Figure 158. Example of Encoder Interface Mode with Inverted Polarity IC1FP1

The timer, when configured in Encoder Interface mode provides information on the sensor’ s current position.The user can obtain dynamic information (speed, acceleration, deceleration) by measuring the period between two encoder events using a second timer configured in capture mode. The output of the encoder which indicates the mechanical zero can be used for this purpose. Depending on the time between two events, the counter can also be read at regular times. This can be done by latching the counter value into a third input capture register if available (then the capture signal must be periodic and can be

generated by another timer). When available, it is also possible to read its value through a DMA request generated by a real-time clock.

13.3.13 Timer input XOR function

The TI1S bit in the TIMx_CR2 register, allows the input filter of channel 1 to be connected to the output of a XOR gate, combining the three input pins TIMx_CH1, TIMx_CH2 and TIMx_CH3.

The XOR output can be used with all the timer input functions such as trigger or input capture. An example of this feature used to interface Hall sensors is given in section 11.3.18.

13.3.14 Timers and external trigger synchronization

The TIMx timer can be synchronized with an external trigger in several modes: Reset mode, Gated mode and Trigger mode.

Slave mode: Reset mode

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx_CR1 register is low, an update event UEV is generated. Then, all the preloaded registers (TIMx_ARR, TIMx_CCRx) are updated.

- In the following example, the upcounter is cleared in response to a rising edge on TI1 input:
- Configure the channel 1 to detect rising edges on TI1. Configure the input filter duration (in this example, we don’t need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so the user does not need to configure it. The CC1S bits select the input capture source only, i.e. CC1S = 01 in the TIMx_CCMR1 register. Write CC1P=0 in TIMx_CCER register to validate the polarity (and detect rising edges only).
- Configure the timer in reset mode by writing SMS=100 in TIMx_SMCR register. Select TI1 as the input source by writing TS=101 in TIMx_SMCR register.
- Start the counter by writing CEN=1 in the TIMx_CR1 register.

The counter starts counting on the internal clock, then behaves normally until TI1 rising edge. When TI1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIMx_SR register) and an interrupt request, or a DMA request can be sent if enabled depending on the TIE (interrupt enable) and TDE (DMA enable) bits in TIMx_DIER register.

The following figure shows this behavior when the auto-reload register TIMx_ARR=0x36. The delay between the rising edge on TI1 and the actual reset of the counter is due to the resynchronization circuit on TI1 input.

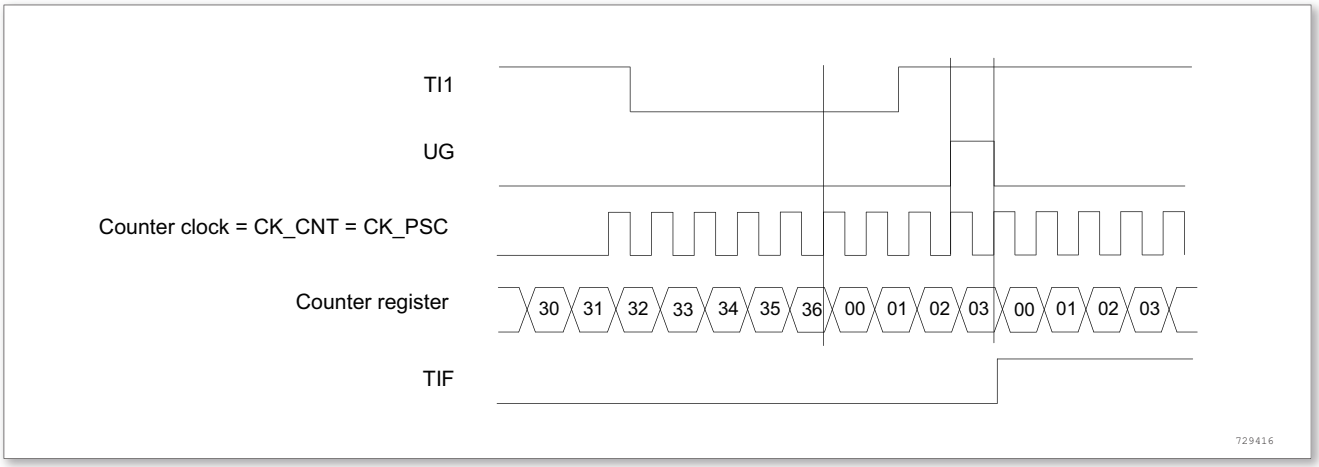

Figure 159. Control Circuit in Reset Mode

Slave mode: Gated mode

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when TI1 input is low:

- Configure the channel 1 to detect low level on TI1. Configure the input filter duration (in this example, we don't need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so the user does not need to configure it. The CC1S bits select the input capture source only, CC1S = 01 in the TIMx_CCMR1 register. Write CC1P=1 in TIMx_CCER register to validate the polarity (and detect low level only).
- Configure the timer in gated mode by writing SMS=101 in TIMx_SMCR register. Select TI1 as the input source by writing TS=101 in TIMx_SMCR register.
- Start the counter by writing CEN=1 in the TIMx_CR1 register. In gated mode, the counter doesn't start if CEN=0, whatever is the trigger input level

The counter starts counting on the internal clock as long as TI1 is low and stops as soon as TI1 becomes high. The TIF flag in the TIMx_SR register is set both when the counter starts or stops.

The delay between the rising edge on TI1 and the actual stop of the counter is due to the resynchronization circuit on TI1 input.

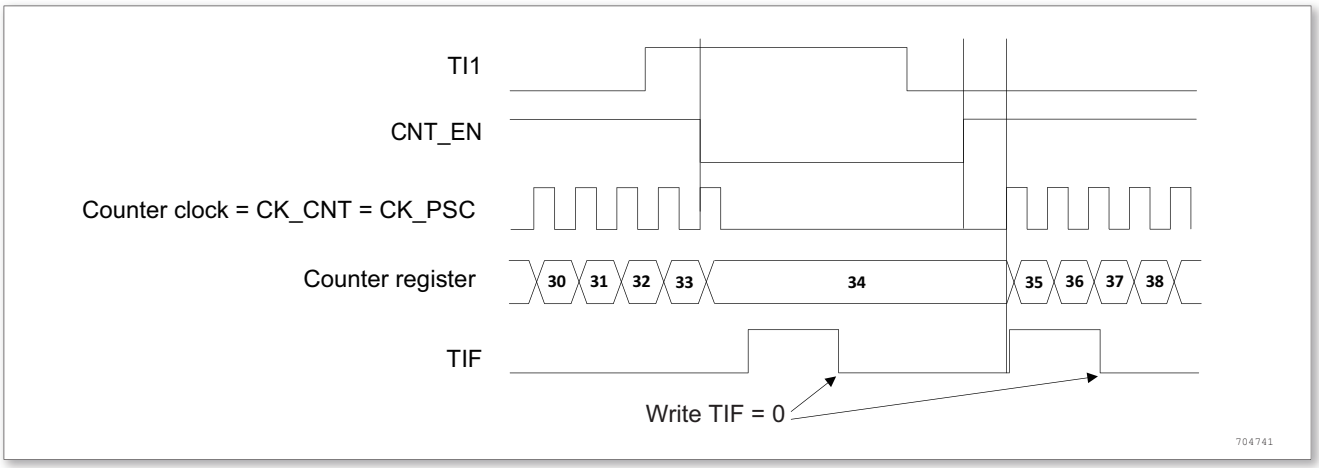

Figure 160. Control Circuit in Gated Mode

Slave mode: Trigger mode

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on TI2 input:

- Configure the channel 2 to detect rising edges on TI2. Configure the input filter duration (in this example, we don't need any filter, so we keep IC2F=0000). The capture prescaler is not used for triggering, so there's no need to configure it. The CC2S bits are only configured to select CC2P=1 in TIMx_CCER register, so as to validate the polarity (and detect low level only).
- Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select TI2 as the input source by writing TS=110 in TIMx_SMCR register.

When a rising edge occurs on TI2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on TI2 and the actual stop of the counter is due to the resynchronization circuit on TI2 input.

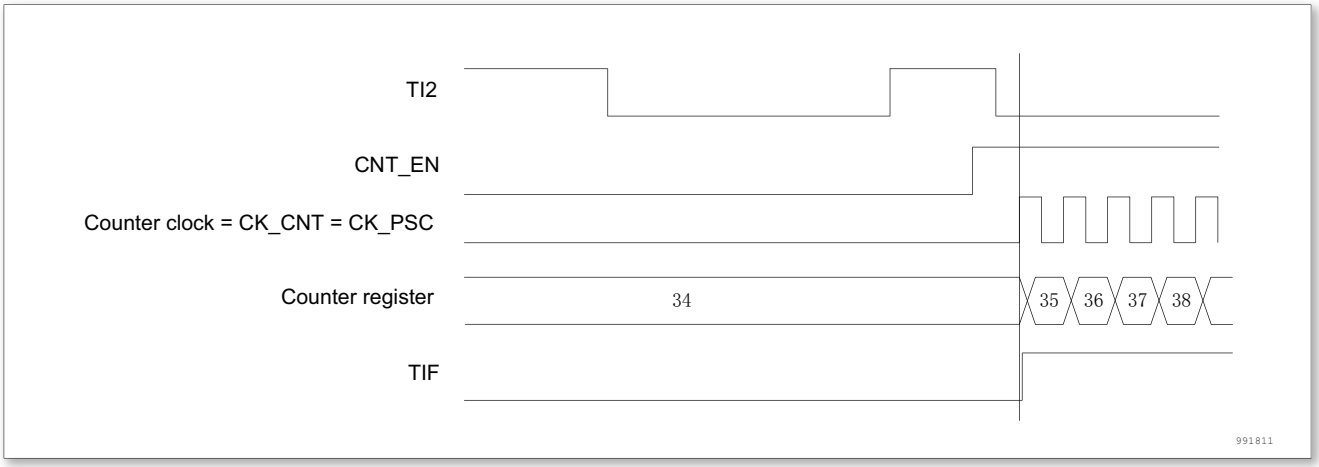

Figure 161. Control Circuit in Trigger Mode

Slave mode: External clock mode 2 + trigger mode

The external clock mode 2 can be used in addition to another slave mode (except external clock mode 1 and encoder mode). In this case, the ETR signal is used as external clock input, and another input can be selected as trigger input (in reset mode, gated mode or trigger mode). It is recommended not to select ETR as TRGI through the TS bits of TIMx_SMCR register.

In the following example, the upcounter is incremented at each rising edge of the ETR signal as soon as a rising edge of TI1 occurs:

- Configure the external trigger input circuit by programming the TIMx_SMCR register as follows:
  - ETF = 0000: no filter
  - ETPS = 00: prescaler disabled
  - ETP = 0: detection of rising edges on ETR and ECE=1 to enable the external clock mode 2.

- Configure the channel 1 as follows, to detect rising edges on T1:
  - IC1F=0000: no filter.
  - The capture prescaler is not used for triggering and does not need to be configured.
  - CC1S=01 in TIMx_CCMR1 register to select only the input capture source.
  - CC1P=0 in TIMx_CCER register to validate the polarity (and detect rising edge only).
- Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select TI1 as the input source by writing TS=101 in TIMx_SMCR register

A rising edge on TI1 enables the counter and sets the TIF flag. The counter then counts on ETR rising edges.

The delay between the rising edge of the ETR signal and the actual reset of the counter is due to the resynchronization circuit on ETRP input.

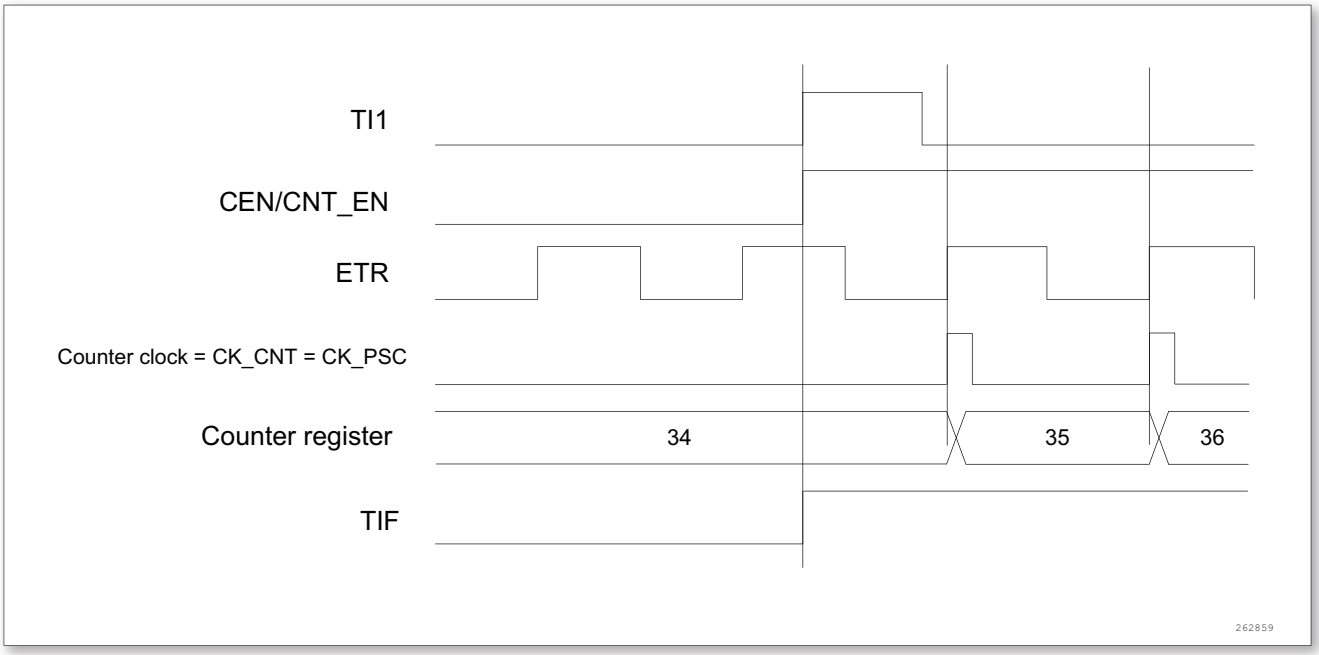

Figure 162. Control Circuit in External Clock Mode 2 + Trigger Mode

13.3.15 Timer synchronization

The TIMx timers are linked together internally for timer synchronization or chaining. When one Timer is configured in Master Mode, it can reset, start, stop or clock the counter of another Timer configured in Slave Mode.

The following figure presents an overview of the trigger selection and the master mode selection blocks.

Using one timer as prescaler for another timer

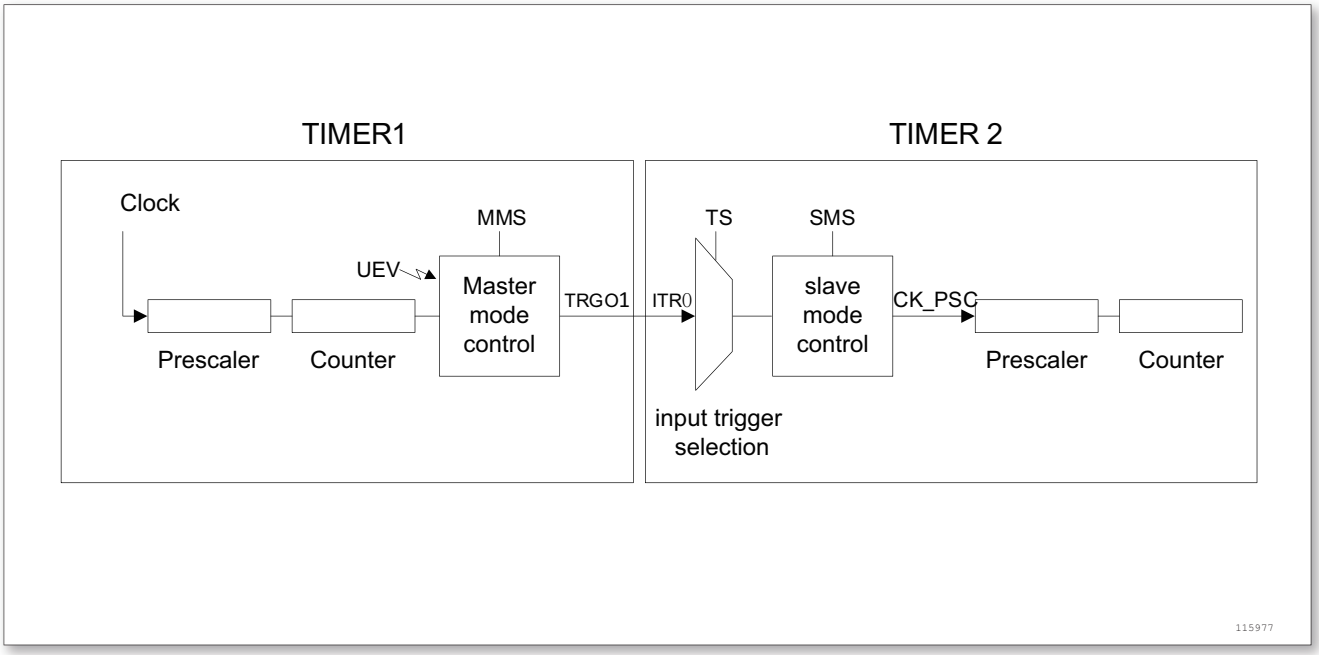

Figure 163. Master/Slave Timer Example

For example, the user can configure Timer 1 to act as a prescaler for Timer 2 (see the above figure). To do this:

- Configure Timer 1 in master mode so that it outputs a periodic trigger signal on each update event UEV. If you write MMS=010 in the TIM1_CR2 register, a rising edge is output on TRGO1 each time an update event is generated.
- To connect the TRGO1 output of Timer 1 to Timer 2, Timer 2 must be configured in slave mode using ITR1 as internal trigger. You select this through the TS bits in the TIM2_SMCR register (writing TS=000).
- Then you put the slave mode controller in external clock mode 1 (write SMS=111 in the TIM2_SMCR register). This causes Timer 2 to be clocked by the rising edge of the periodic Timer 1 trigger signal (which corresponds to the Timer 1 counter overflow).
- Finally, both timers must be enabled by setting their respective CEN bits (TIMx_CR1 register).

Note: If OCx is selected on Timer 1 as trigger output (MMS=1xx), its rising edge is used to clock the counter of Timer 2.

Using one timer to enable another timer

In this example, we control the enable of Timer 2 with the output compare 1 of Timer 1. Refer to Figure 164 for connections. Timer 2 counts on the divided internal clock only when OC1REF of Timer 1 is high. Both counter clock frequencies are divided by 3 by the prescaler compared to CK_INT ($f_{CK\_CNT} = f_{CK\_INT/3}$).

- Configure Timer 1 master mode to send its Output Compare 1 Reference (OC1REF) signal as trigger output (MMS=100 in the TIM1_CR2 register).
- Configure the Timer 1 OC1REF waveform (TIM1_CCMR1 register).
- Configure Timer 2 to get the input trigger from Timer 1 (TS=001 in the TIM2_SMCR

register).

- Configure Timer 2 in gated mode (SMS=101 in TIM2_SMCR register).
- Enable Timer 2 by writing ‘1 in the CEN bit (TIM2_CR1 register).
- Enable Timer 1 by writing ‘1 in the CEN bit (TIM1_CR1 register).

Note: The counter 2 clock is not synchronized with counter 1, this mode only affects the Timer 2 counter enable signal.

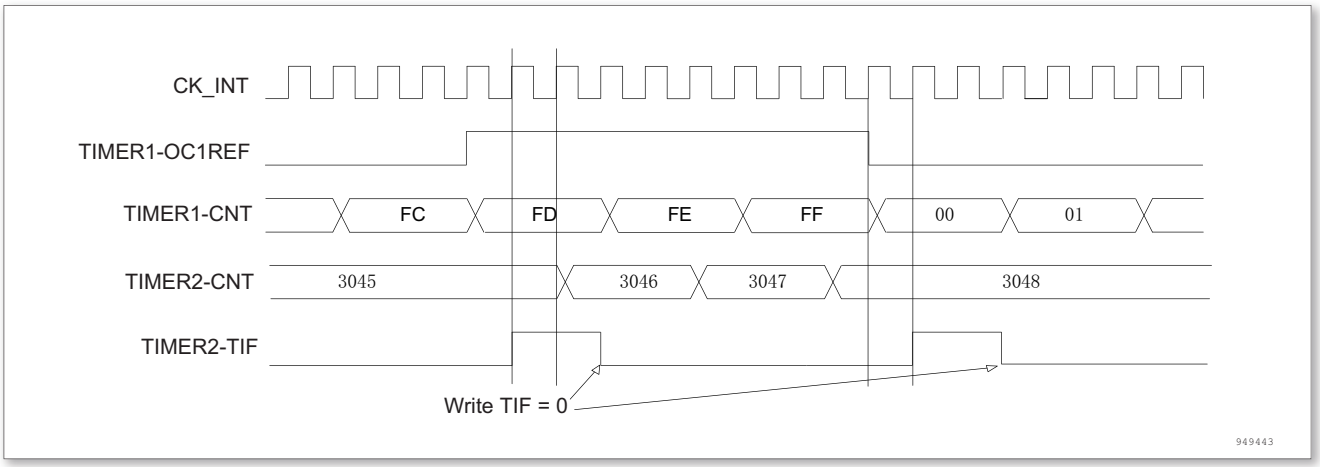

Figure 164. Gating Timer 2 with OC1REF of Timer 1

In the example in the above figure, the Timer 2 counter and prescaler are not initialized before being started. So they start counting from their current value. It is possible to start from a given value by resetting both timers before starting Timer 1. You can then write any value you want in the timer counters. The timers can easily be reset by software using the UG bit in the TIMx_EGR registers.

In the next example, we synchronize Timer 1 and Timer 2. Timer 1 is the master and starts from 0. Timer 2 is the slave and starts from 0xE7. The prescaler ratio is the same for both timers. Timer 2 stops when Timer 1 is disabled by writing ‘0 to the CEN bit in the TIM1_CR1 register:

- Configure Timer 1 master mode to send its Output Compare 1 Reference (OC1REF) signal as trigger output (MMS=100 in the TIM1_CR2 register).
- Configure the Timer 1 OC1REF waveform (TIM1_CCMR1 register).
- Configure Timer 2 to get the input trigger from Timer 1 (TS=000 in the TIM2_SMCR register).
- Configure Timer 2 in gated mode (SMS=101 in TIM2_SMCR register).
- Reset Timer 1 by writing ‘1 in UG bit (TIM1_EGR register).
- Reset Timer 2 by writing ‘1 in UG bit (TIM2_EGR register).
- Initialize Timer 2 to 0xE7 by writing ‘0xE7’ in the Timer 2 counter (TIM2_CNT).
- Enable Timer 2 by writing ‘1 in the CEN bit (TIM2_CR1 register).
- Start Timer 1 by writing ‘1 in the CEN bit (TIM1_CR1 register).
- Stop Timer 1 by writing ‘0 in the CEN bit (TIM1_CR1 register).

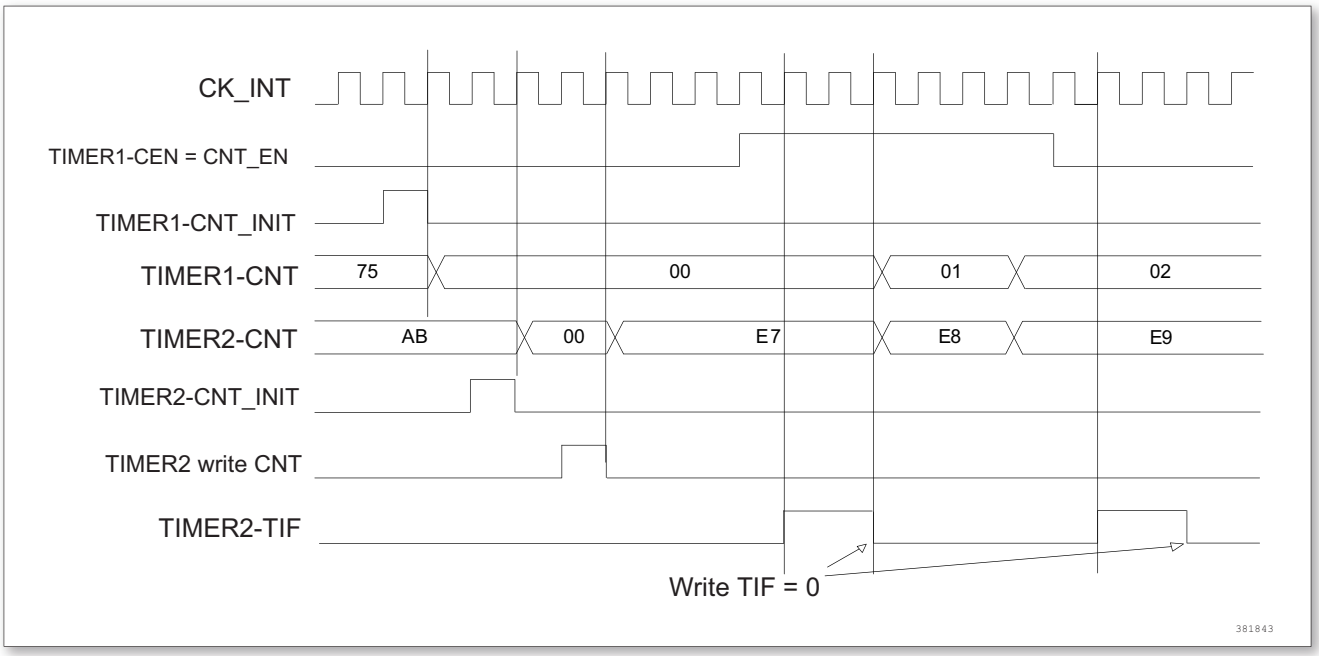

Figure 165. Gating Timer 2 with Enable of Timer 1

Using one timer to start another timer

In this example, we set the enable of Timer 2 with the update event of Timer 1. Refer to the following figure for connections. Timer 2 starts counting from its current value (which can be nonzero) on the divided internal clock as soon as the update event is generated by Timer 1.

When Timer 2 receives the trigger signal its CEN bit is automatically set and the counter counts until we write '0' to the CEN bit in the TIM2_CR1 register. Both counter clock frequencies are divided by 3 by the prescaler compared to CK_INT ($f_{CK\_CNT} = f_{CK\_INT/3}$).

- Configure Timer 1 master mode to send its Update Event (UEV) as trigger output (MMS=010 in the TIM1_CR2 register).
- Configure the Timer 1 period (TIM1_ARR registers).
- Configure Timer 2 to get the input trigger from Timer 1 (TS=000 in the TIM2_SMCR register).
- Configure Timer 2 in trigger mode (SMS=110 in TIM2_SMCR register).
- Start Timer 1 by writing '1' in the CEN bit (TIM1_CR1 register)

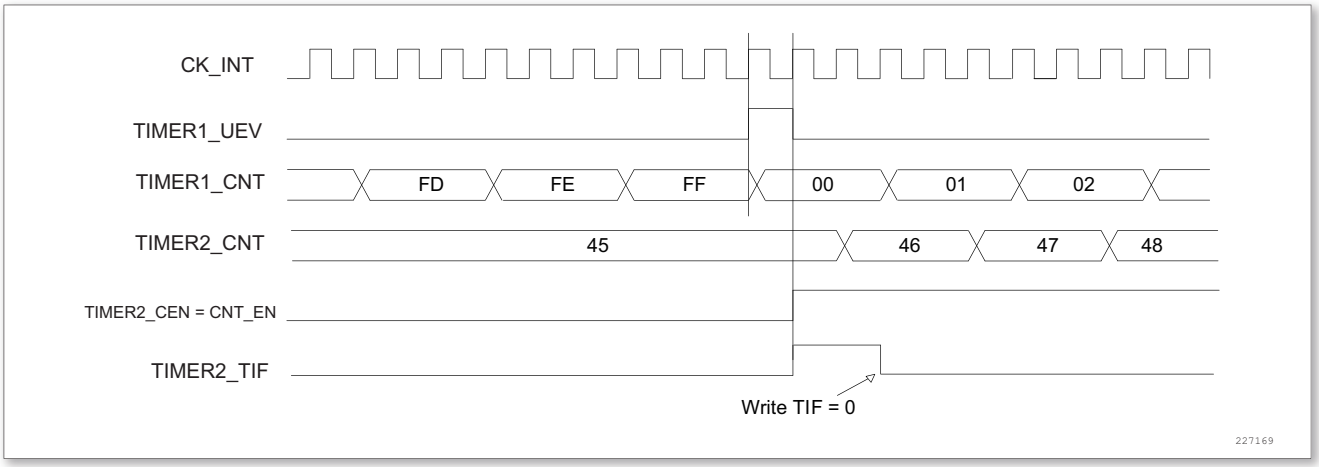

Figure 166. Triggering Timer 2 with Update of Timer 1

As in the previous example, the user can initialize both counters before starting counting. The following figure shows the behavior with the same configuration as ’0’ but in trigger mode instead of gated mode (SMS=110 in the TIM2_SMCR register).

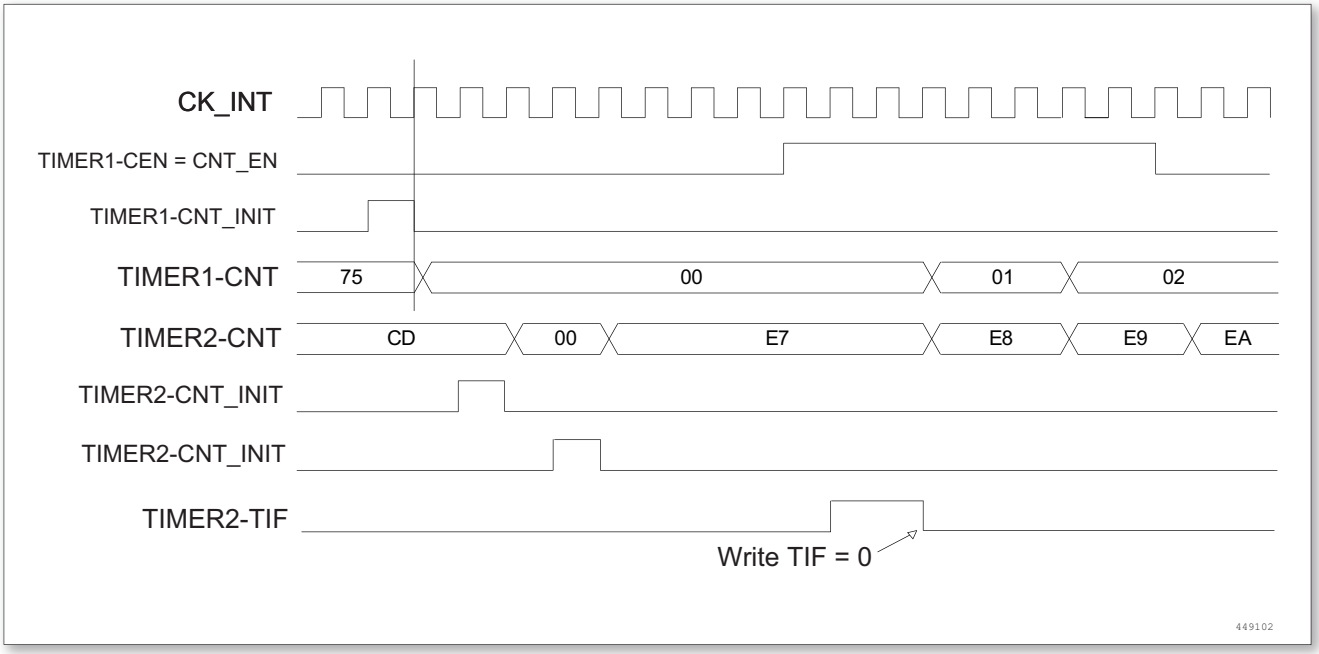

Figure 167. Triggering Timer 2 with Enable of Timer 1

Using one additional timer as prescaler for another timer

In this example, we use Timer 1 as the prescaler for Timer 2. The configuration is as follows:

- Configure Timer 1 in master mode, togenerate the update event (UEV) as the trigger output (MMS=010 in the TIM1_CR2 register). Then, output a periodic signal in case of each counter overflow.
- Configure the Timer 1 period (TIM1_ARR registers).
- Configure Timer 2 to get the input trigger from Timer 1 (TS=000 in the TIM2_SMCR register).
- Configure Timer 2 in the external clock mode (write SMS=111 in the TIM2_SMCR reg-

ister).

- Start Timer 2 by writing ’1’ in the CEN bit (TIM1_CR2 register)
- Start Timer 1 by writing ’1’ in the CEN bit (TIM1_CR1 register).

Starting 2 timers synchronously in response to an external trigger

In this example, we set the enable of timer 1 when its TI1 input rises, and the enable of Timer 2 with the enable of Timer 1. To ensure the counters are aligned, Timer 1 must be configured in Master/Slave mode (slave with respect to TI1, master with respect to Timer 2):

- Configure Timer 1 master mode to send its Enable as trigger output (MMS=001 in the TIM1_CR2 register).
- Configure Timer 1 slave mode to get the input trigger from TI1 (TS=100 in the TIM1_SMCR register).
- Configure Timer 1 in trigger mode (SMS=110 in the TIM1_SMCR register).
- Configure Timer 2 to get the input trigger from Timer 1 (TS=000 in the TIM2_SMCR register).
- Configure Timer 2 in trigger mode (SMS=110 in the TIM2_SMCR register).

When a rising edge occurs on TI1 (Timer 1), both counters starts counting synchronously on the internal clock and both TIF flags are set. Note: In this example both timers are initialized before starting (by setting their respective UG bits). Both counters starts from 0, but you can easily insert an offset between them by writing any of the counter registers (TIMx_CNT). You can see that the master/slave mode insert a delay between CNT_EN and CK_PSC on timer 1.

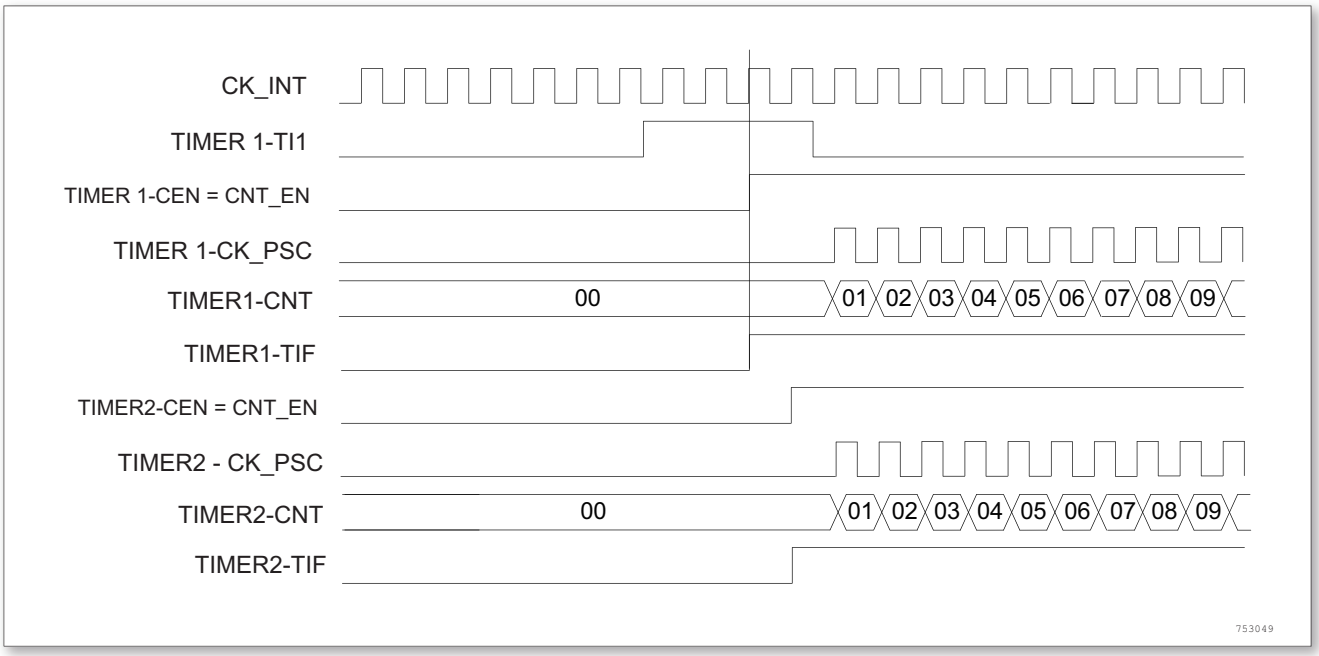

Figure 168. Triggering Timer 1 and 2 with Timer 1 TI1 input

13.3.16 Debug mode

When the microcontroller enters debug mode (CPU core - halted), the TIMx counter either continues to work normally or stops, depending on DBG_TIMx_STOP configuration bit in

DBG module. For more details, refer to ”Debug” sections.

13.4 TIMx register description

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

13.4.1 Control register 1(TIMx_CR1)

Offset address: 0x00

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						CKD		ARPE	CMS		DIR	OPM	URS	UDIS	CEN
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit	Field	Type	Reset	Description
15: 10	Reserved			Reserved, always read as 0.

Bit	Field	Type	Reset	Description
9: 8	CKD	rw	0x00	Clock division The 2 bits indicates the division ratio between the timer clock (CK_INT) frequency and the dead-time and sampling clock used by the dead-time generators and the digital filters (ETR, TIx). 00: $t_{DTS} = t_{CK\_INT}$ 01: $t_{DTS} = 2 \times t_{CK\_INT}$ 10: $t_{DTS} = 4 \times t_{CK\_INT}$ 11: Reserved, do not program this value
7	ARPE	rw	0x00	Auto-reload preload enable 0: TIMx_ARR register is not buffered 1: TIMx_ARR register is buffered
6: 5	CMS	rw	0x00	Center-aligned mode selection 00: Edge-aligned mode. The counter counts up or down depending on the direction bit (DIR). 01: Center-aligned mode 1. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set only when the counter is counting down. 10: Center-aligned mode 2. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set only when the counter is counting up. 11: Center-aligned mode 3. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set both when the counter is counting up or down. Note: It is not allowed to switch from edge-aligned mode to center-aligned mode as long as the counter is enabled (CEN=1).
4	DIR	rw	0x00	Direction 0: Counter used as upcounter 1: Counter used as downcounter Note: This bit is read only when the timer is configured in Center-aligned mode or Encoder mode.
3	OPM	rw	0x00	One pulse mode 0: Counter is not stopped at update event 1: Counter stops counting at the next update event (clearing the bit CEN)

Bit	Field	Type	Reset	Description
2	URS	rw	0x00	Update request source This bit is set and cleared by software to select the UEV event sources. 0: Any of the following events generates an update interrupt or DMA request if enabled.These events can be: - Counter overflow/underflow - Setting the UG bit - Update generation through the slave mode controller 1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.
1	UDIS	rw	0x00	Update disable This bit is set and cleared by software to enable/disable UEV event generation. 0: UEV enabled. The Update (UEV) event is generated by one of the following events: - Counter overflow/underflow - Setting the UG bit - Update generation through the slave mode controller, buffered registers are then loaded with their preload values 1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.
0	CEN	rw	0x00	Counter enable 0: Counter disabled 1: Counter enabled Note: External clock, gated mode and encoder mode can work only if the CEN bit has been previously set by software. However, trigger mode can set the CEN bit automatically by hardware.

13.4.2 Control register 2(TIMx_CR2)

Offset address: 0x04

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								TI1S	MMS			CCDS	Reserved		
								rw	rw	rw	rw	rw			

Bit	Field	Type	Reset	Description
15: 8	Reserved			Reserved, always read as 0.
7	TI1S	rw	0x00	TI1 selection 0: The TIMx_CH1 pin is connected to TI1 input 1: The TIMx_CH1, CH2 and CH3 pins are connected to the TI1 input (XOR combination)
6: 4	MMS	rw	0x00	Master mode selection These bits allow to select the information to be sent in master mode to slave timers for synchronization (TRGO). The combination is as follows: 000: Reset - the UG bit from the TIMx_EGR register is used as trigger output (TRGO). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on TRGO is delayed compared to the actual reset. 001: Enable - the Counter Enable signal CNT_EN is used as trigger output (TRGO). It is useful to start several timers at the same time or to control a window in which a slave timer is enable. The Counter Enable signal is generated by a logic OR between CEN control bit and the trigger input when configured in gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on TRGO, except if the master/slave mode is selected (see the MSM bit description in TIMx_SMCR register). 010: Update - The update event is selected as trigger output (TRGO). For instance, a master timer can then be used as a prescaler for a slave timer. 011: Compare Pulse - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred (TRGO). 100: Compare - OC1REF signal is used as trigger output (TRGO) 101: Compare - OC2REF signal is used as trigger output (TRGO) 110: Compare - OC3REF signal is used as trigger output (TRGO) 111: Compare - OC4REF signal is used as trigger output (TRGO)
3	CCDS	rw	0x00	Capture/compare DMA selection 0: CCx DMA request sent when CCx event occurs 1: CCx DMA requests sent when update event occurs

Bit	Field	Type	Reset	Description
2: 0	Reserved			Reserved, always read as 0.

13.4.3 Slave mode control register(TIMx_SMCR)

Offset address: 0x08

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ETP	ECE	ETPS		ETF				MSM	TS			Res.	SMS		
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		rw	rw	rw

Bit	Field	Type	Reset	Description
15	ETP	rw	0x00	External trigger polarity This bit selects whether ETR or inverted ETR is used for trigger operations. 0: ETR is non-inverted, active at high level or rising edge. 1: ETR is inverted, active at low level or falling edge.
14	ECE	rw	0x00	External clock enable This bit enables External clock mode 2. 0: External clock mode 2 disabled 1: External clock mode 2 enabled. The counter is clocked by any active edge on the ETRF signal. Note 1: Setting the ECE bit has the same effect as selecting external clock mode 1 with TRGI connected to ETRF (SMS=111 and TS=111). Note 2: It is possible to simultaneously use external clock mode 2 with the following slave modes: reset mode, gated mode and trigger mode. Nevertheless, TRGI must not be connected to ETRF in this case (TS bits must not be 111). Note 3: If external clock mode 1 and external clock mode 2 are enabled at the same time, the external clock input is ETRF.
13: 12	ETPS	rw	0x00	External trigger prescaler External trigger signal ETRP frequency must be at most 1/4 of TIMxCLK frequency. A prescaler can be enabled to reduce ETRP frequency. It is useful when inputting fast external clocks. 00: Prescaler OFF 01: ETRP frequency divided by 2 10: ETRP frequency divided by 4 11: ETRP frequency divided by 8

Bit	Field	Type	Reset	Description
11: 8	ETF	rw	0x00	External trigger filter This bit-field then defines the frequency used to sample ETRP signal and the length of the digital filter applied to ETRP. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output: 0000: No filter, sampling is done at f_{DTS}. 0001: sampling frequency $f_{SAMPLING}=f_{CK\_INT}$, N = 2 0010: sampling frequency $f_{SAMPLING}=f_{CK\_INT}$, N = 4 0011: sampling frequency $f_{SAMPLING}=f_{CK\_INT}$, N = 8 0100: sampling frequency $f_{SAMPLING}=f_{DTS}/2$, N = 6 0101: sampling frequency $f_{SAMPLING}=f_{DTS}/2$, N = 8 0110: sampling frequency $f_{SAMPLING}=f_{DTS}/4$, N = 6 0111: sampling frequency $f_{SAMPLING}=f_{DTS}/4$, N = 8 1000: sampling frequency $f_{SAMPLING}=f_{DTS}/8$, N = 6 1001: sampling frequency $f_{SAMPLING}=f_{DTS}/8$, N = 8 1010: sampling frequency $f_{SAMPLING}=f_{DTS}/16$, N = 5 1011: sampling frequency $f_{SAMPLING}=f_{DTS}/16$, N = 6 1100: sampling frequency $f_{SAMPLING}=f_{DTS}/16$, N = 8 1101: sampling frequency $f_{SAMPLING}=f_{DTS}/32$, N = 5 1110: sampling frequency $f_{SAMPLING}=f_{DTS}/32$, N = 6 1111: sampling frequency $f_{SAMPLING}=f_{DTS}/32$, N = 8
7	MSM	rw	0x00	Master/slave mode 0: No action 1: The effect of an event on the trigger input (TRGI) is delayed to allow a perfect synchronization between the current timer and its slaves (through TRGO). It is useful if we want to synchronize several timers on a single external event.

Bit	Field	Type	Reset	Description
6: 4	TS	rw	0x00	Trigger selection This bit-field selects the trigger input to be used to synchronize the counter. 000: Internal Trigger 0 (ITR0) 001: Internal Trigger 1(ITR1) 010: Internal Trigger 2(ITR2) 011: Internal Trigger 3(ITR3) 100: TI1 Edge Detector (TI1F_ED) 101: Filtered Timer Input 1 (TI1FP1) 110: Filtered Timer Input 2(TI2FP2) 111: External Trigger input (ETRF) See the following table for more details on ITRx. Note: These bits must be changed only when they are not used (e.g. when SMS=000) to avoid wrong edge detections at the transition.
3	Reserved			Reserved, always read as 0.

Bit	Field	Type	Reset	Description
2: 0	SMS	rw	0x00	Slave mode selection When external signals are selected the active edge of the trigger signal (TRGI) is linked to the polarity selected on the external input (refer to Input Control register and Control Register description). 000: Slave mode disabled - if CEN = '1' then the prescaler is clocked directly by the internal clock. 001: Encoder mode 1 - Counter counts up/down on TI2FP1 edge depending on TI1FP2 level. 010: Encoder mode 2 - Counter counts up/down on TI1FP2 edge depending on TI2FP1 level. 011: Encoder mode 3 - Counter counts up/down on both TI1FP1 and TI2FP2 edges depending on the level of the other input. 100: Reset Mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter and generates an update of the registers. 101: Gated Mode - The counter clock is enabled when the trigger input (TRGI) is high. The counter stops (but is not reset) as soon as the trigger input becomes low. Both start and stop of the counter are controlled. 110: Trigger Mode - The counter starts at a rising edge of the trigger TRGI (but it is not reset). Only the start of the counter is controlled. 111: External Clock Mode 1 - Rising edges of the selected trigger input (TRGI) clock the counter. Note: The gated mode must not be used if TI1F_EN is selected as the trigger input (TS= '100'). Indeed, TI1F_ED outputs 1 pulse for each transition on TI1F, whereas the gated mode checks the level of the trigger signal.

Bit	Field	Type	Reset	Description
15: 13	Reserved			Reserved, always read as 0.
12	CC4OF	rc_w0	0x00	Capture/Compare 4 overcapture flag Refer to CC1OF description.
11	CC3OF	rc_w0	0x00	Capture/Compare 3 overcapture flag Refer to CC1OF description.
10	CC2OF	rc_w0	0x00	Capture/Compare 2 overcapture flag Refer to CC1OF description.
9	CC1OF	rc_w0	0x00	Capture/Compare 1 overcapture flag This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to ‘0’. 0: No overcapture has been detected. 1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set.
8: 7	Reserved			Reserved, always read as 0.
6	TIF	rc_w0	0x00	Trigger interrupt flag This flag is set by hardware on trigger event (active edge detected on TRGI input when the slave mode controller is enabled in all modes but gated mode, both edges in case gated mode is selected). It is cleared by software. 0: No trigger event occurred. 1: Trigger interrupt pending.
5	Reserved			Reserved, always read as 0.
4	CC4IF	rc_w0	0x00	Capture/Compare 4 interrupt flag Refer to CC1IF description.
3	CC3IF	rc_w0	0x00	Capture/Compare 3 interrupt flag Refer to CC1IF description.
2	CC2IF	rc_w0	0x00	Capture/Compare 2 interrupt flag Refer to CC1IF description.

Bit	Field	Type	Reset	Description
1	CC1IF	rc_w0	0x00	Capture/Compare 1 interrupt flag If channel CC1 is configured as output: This flag is set by hardware when the counter matches the compare value, with some exception in center-aligned mode (refer to the CMS bits in the TIMx_CR1 register description). It is cleared by software. 0: No match 1: The content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register. If channel CC1 is configured as input: This bit is set by hardware on a capture. It is cleared by software or by reading the TIMx_CCR1 register. 0: No input capture occurred 1: The counter value has been captured in TIMx_CCR1 register (An edge has been detected on IC1 which matches the selected polarity)
0	UIF	rc_w0	0x00	Update interrupt flag This bit is set by hardware on an update event. It is cleared by software. 0: No update occurred. 1: Update interrupt pending. This bit is set by hardware when the registers are updated: - At overflow or underflow regarding the repetition counter value (update if repetition counter= 0) and if the UDIS=0 in the TIMx_CR1 register. – When CNT is reinitialized by software using the UG bit in TIMx_EGR register, if URS=0 and UDIS=0 in the TIMx_CR1 register. –When CNT is reinitialized by a trigger event (refer to the description of synchronization control register), if URS=0 and UDIS=0 in the TIMx_CR1 register.

Bit	Field	Type	Reset	Description
15: 7	Reserved			Reserved, always read as 0.

Bit	Field	Type	Reset	Description
6	TG	w	0x00	Trigger generation This bit is set by software in order to generate an event, it is automatically cleared by hardware. 0: No action 1: The TIF flag is set in TIMx_SR register. Related interrupt or DMA transfer can occur if enabled.
5	Reserved			Reserved, always read as 0.
4	CC4G	w	0x00	Capture/Compare 4 generation Refer to CC1G description.
3	CC3G	w	0x00	Capture/Compare 3 generation Refer to CC1G description.
2	CC2G	w	0x00	Capture/Compare 2 generation Refer to CC1G description.
1	CC1G	w	0x00	Capture/Compare 1 generation This bit is set by software in order to generate an event, it is automatically cleared by hardware. 0: No action 1: A capture/compare event is generated on channel 1: If channel CC1 is configured as output: CC1IF flag is set, Corresponding interrupt or DMA request is sent if enabled. If channel CC1 is configured as input: The current value of the counter is captured in TIMx_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.
0	UG	w	0x00	Update generation This bit can be set by software, it is automatically cleared by hardware. 0: No action 1: Reinitialize the counter and generate an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler factor is not affected). The counter is cleared if the center-aligned mode is selected or if DIR=0 (upcounting), otherwise, it takes the auto-reload value (TIMx_ARR) if DIR=1 (downcounting).

13.4.7 Capture/compare mode register 1(TIMx_CCMR1)

Offset address: 0x18

Reset value: 0x0000

The channels can be used in input (capture mode) or in output (compare mode). The

direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode. For a given bit, OCxx describes its function when the channel is configured in output, ICxx describes its function when the channel is configured in input. So the user must take care that the same bit can have a different meaning for the input stage and for the output stage.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Output compare mode:

Bit	Field	Type	Reset	Description
15	OC2CE	rw	0x00	Output compare 2 clear enable
14: 12	OC2M	rw	0x00	Output compare 2 mode
11	OC2PE	rw	0x00	Output compare 2 preload enable
10	OC2FE	rw	0x00	Output compare 4 fast enable
9: 8	CC2S	rw	0x00	Capture/Compare 2 selection This bit-field defines the direction of the channel (input/output) as well as the input pin. 00: CC2 channel is configured as output 01: CC2 channel is configured as input, IC2 is mapped on TI2 10: CC2 channel is configured as input, IC2 is mapped on TI1 11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through the TS bit (TIMx_SMCR register) Note: CC2S bits are writable only when the channel is OFF (CC2E = ‘0’ in TIMx_CCER).
7	OC1CE	rw	0x00	Output compare 1 clear enable 0: OC1Ref is not affected by the ETRF Input 1: OC1Ref is cleared as soon as a High level is detected on ETRF input

Bit	Field	Type	Reset	Description
6: 4	OC1M	rw	0x00	Output compare 1 mode These bits define the behavior of the output reference signal OC1REF from which OC1 and OC1N are derived. OC1REF is active high whereas OC1 and OC1N active level depends on CC1P and CC1NP bits. 000: Frozen - The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs 001: Set channel 1 to active level on match. OC1REF signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1). 010: Set channel 1 to inactive level on match. OC1REF signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1). 011: Toggle - OC1REF toggles when TIMx_CNT=TIMx_CCR1. 100: Force inactive level - OC1REF is forced low. 101: Force active level - OC1REF is forced high. 110: PWM mode 1 - In upcounting, channel 1 is active as long as TIMx_CNT<TIMx_CCR1 otherwise inactive. In downcounting, channel 1 is inactive (OC1REF=‘0’) as long as TIMx_CNT>TIMx_CCR1 otherwise active (OC1REF=’1’). 111: PWM mode 2 - In upcounting, channel 1 is inactive as long as TIMx_CNT<TIMx_CCR1otherwise active. In downcounting, channel 1 is active as long as TIMx_CNT>TIMx_CCR1 otherwise inactive. Note 1: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S=’00’(the channel is configured in output). Note 2: In PWM mode 1 or 2, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from “frozen” mode to “PWM” mode.

Bit	Field	Type	Reset	Description
3	OC1PE	rw	0x00	Output compare 1 preload enable 0: Preload register on TIMx_CCR1 disabled. TIMx_CCR1 can be written at anytime, the new value is taken in account immediately. 1: Preload register on TIMx_CCR1 enabled. Read/Write operations access the preload register. TIMx_CCR1 preload value is loaded in the active register at each update event. Note 1: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S=’00’ (the channel is configured in output). Note 2: The PWM mode can be used without validating the preload register only in one pulse mode (OPM bit set in TIMx_CR1 register). Else the behavior is not guaranteed.
2	OC1FE	rw	0x00	Output compare 1 fast enable This bit is used to accelerate the effect of an event on the trigger in input on the CC output. 0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles. 1: An active edge on the trigger input acts like a compare match on CC1 output. Then, OC is set to the compare level independently from the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OCFE acts only if the channel is configured in PWM1 or PWM2 mode.
1: 0	CC1S	rw	0x00	Capture/Compare 1 selection This bit-field defines the direction of the channel (input/output) as well as the input pin. 00: CC1 channel is configured as output 01: CC1 channel is configured as input, IC1 is mapped on TI1 10: CC1 channel is configured as input, IC1 is mapped on TI2 11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register) Note: CC1S bits are writable only when the channel is OFF (CC1E = ’0’ in TIMx_CCER).

Input capture mode:

Bit	Field	Type	Reset	Description
15: 12	IC2F	rw	0x00	Input capture 2 filter
11: 10	IC2PSC	rw	0x00	Input capture 2 prescaler
9: 8	CC2S	rw	0x00	Capture/Compare 2 selection This bit-field defines the direction of the channel (input/output) as well as the input pin. 00: CC2 channel is configured as output 01: CC2 channel is configured as input, IC2 is mapped on TI2 10: CC2 channel is configured as input, IC2 is mapped on TI1 11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through the TS bit (TIMx_SMCR register) Note: CC2S bits are writable only when the channel is OFF (CC2E = '0' in TIMx_CCER).
7: 4	IC1F	rw	0x00	Input capture 1 filter This bit-field defines the frequency used to sample TI1 input and the length of the digital filter applied to TI1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output: 0000: No filter, sampling is done at f_{DTS} 1000: sampling frequency $f_{SAMPLING}=f_{DTS}/8$, N = 6 0001: sampling frequency $f_{SAMPLING}=f_{CK\_INT}$, N = 2 1001: sampling frequency $f_{SAMPLING}=f_{DTS}/8$, N = 8 0010: sampling frequency $f_{SAMPLING}=f_{CK\_INT}$, N = 4 1010: sampling frequency $f_{SAMPLING}=f_{DTS}/16$, N = 5 0011: sampling frequency $f_{SAMPLING}=f_{CK\_INT}$, N = 8 1011: sampling frequency $f_{SAMPLING}=f_{DTS}/16$, N = 6 0100: sampling frequency $f_{SAMPLING}=f_{DTS}/2$, N = 6 1100: sampling frequency $f_{SAMPLING}=f_{DTS}/16$, N = 8 0101: sampling frequency $f_{SAMPLING}=f_{DTS}/2$, N = 8 1101: sampling frequency $f_{SAMPLING}=f_{DTS}/32$, N = 5 0110: sampling frequency $f_{SAMPLING}=f_{DTS}/4$, N = 6 1110: sampling frequency $f_{SAMPLING}=f_{DTS}/32$, N = 6 0111: sampling frequency $f_{SAMPLING}=f_{DTS}/4$, N = 8 1111: sampling frequency $f_{SAMPLING}=f_{DTS}/32$, N = 8

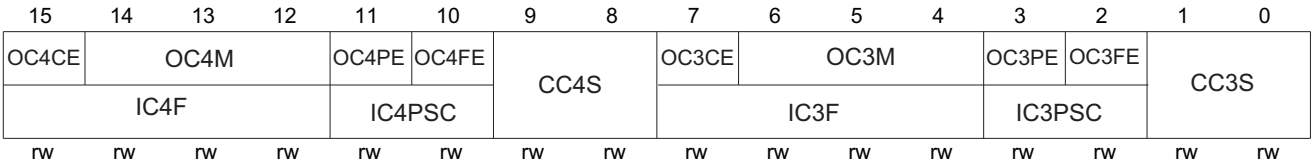
Bit	Field	Type	Reset	Description
3: 2	IC1PSC	rw	0x00	Input capture 1 prescaler This bit-field defines the factor of the prescaler acting on CC1 input (IC1). The prescaler is reset as soon as CC1E=’0’(TIMx_CCER register). 00: no prescaler, capture is done each time an edge is detected on the capture input. 01: capture is done once every 2 events 10: capture is done once every 4 events 11: capture is done once every 8 events
1: 0	CC1S	rw	0x00	Capture/compare 1 selection This bit-field defines the direction of the channel (input/output) as well as the input pin. 00: CC1 channel is configured as output 01: CC1 channel is configured as input, IC1 is mapped on TI1 10: CC1 channel is configured as input, IC1 is mapped on TI2 11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through the TS bit (TIMx_SMCR register) Note: CC1S bits are writable only when the channel is OFF (CC1E = ‘0’ in TIMx_CCER).

13.4.8 Capture/compare mode register 2(TIMx_CCMR2)

Offset address: 0x1C

Reset value: 0x0000

Refer to the above CCMR1 register description.



Output compare mode:

Bit	Field	Type	Reset	Description

15: 0	CCR4	rw	0x0000	Low Capture/Compare 4 value If CC4 channel is configured as output: CCR4 contains the value to be loaded in the actual capture/compare 4 register (preload value). The written value is transferred to the current register immediately if the preload feature is not selected in the TIMx_CCMR4 register (bit OC4PE). Otherwise the preload value is copied in the active capture/compare 4 register when an update event occurs. The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on OC4 output. If CC4 channel is configured as input: CCR4 contains the counter value transferred by the last input capture 4 event (IC4).

13.4.17 DMA control register(TIMx_DCR)

Offset address: 0x48

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.			DBL					Res.			DBA				
			w	w	w	w	w				w	w	w	w	w

Bit	Field	Type	Reset	Description
15: 13	Reserved			Reserved, always read as 0.
12: 8	DBL	w	0x00	DMA burst length This bit field defines the burst transfer in the continuous mode (the timer detects a burst transfer when a write access to the TIMx_DMAR register address is performed), namely, the number of transfers, in half-word (double bytes) or bytes. 00000: 1 transfer 00001: 2 transfers 00010: 3 transfers .... 10001: 18 transfers Example: Let us consider the following transfer: DBL = 7 and DBA = TIM2_CR1. - If DBL =7 and DBA = TIM2_CR1 represent the address of data to be transferred, the transfer address is given by: (Address of TIMx_CR1) + DBA + (DMA index), where, DMA index = DBL TIMx_CR1 address + DBA + 7 is the address of data to be written or read, so that the transfer is completed to/from 7 registers starting from the TIMx_CR1 address + DBA. According to the setting of DMA data length, the following case may occur: -If the data is set to half word (16 bits), the data will be transferred to all 7 registers. -If the data is set to bytes, the data will still be transferred to all 7 registers: the first register contains the first MSB byte, the second register contains the first LSB byte, and so on. Therefore, the user must specify the data width of DMA transfer for the timer.
7: 5	Reserved			Reserved, always read as 0.

Bit	Field	Type	Reset	Description
4: 0	DBA	w	0x00	DMA base address These bits define the base-address for DMA transfers in the continuous mode (when write access is done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register. 00000: TIMx_CR1 00001: TIMx_CR2 00010: TIMx_SMCR .....

Bit	Field	Type	Reset	Description
15: 0	DMAB	w	0x0000	DMA register for burst accesses A write operation to the TIMx_DMAR register will access the register located at the following address: TIMx_CR1 address + DBA + DMA index, Where: ‘TIMx_CR1 address’ is the address of the control register 1; ‘DBA’ is the DMA base address configured in TIMx_DCR register; ‘DMA index’ is the offset automatically controlled by the DMA transfer, depending on DBL configured in TIMx_DCR.

14 Basic timer(TIM14)

Basic timer(TIM14)

14.1 TIM14 introduction

Basic timer TIM14 consist of a 16-bit auto-reload counter driven by a programmable prescaler.

It may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare and PWM).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

TIM14 are completely independent, and do not share any resources.

14.2 TIM14 Main features

- 16-bit auto-reload register
- 16-bit programmable prescaler allowing dividing (modifing in real time) the counter clock frequency either by any factor between 1 and 65536.
- Independent channels for:
  - Input capture
  - Output compare
  - PWM generation (Edge Mode)
- Interrupt/DMA generation on the following events:
  - Update: counter overflow, counter initialization (by software)
  - Input capture
  - Output compare

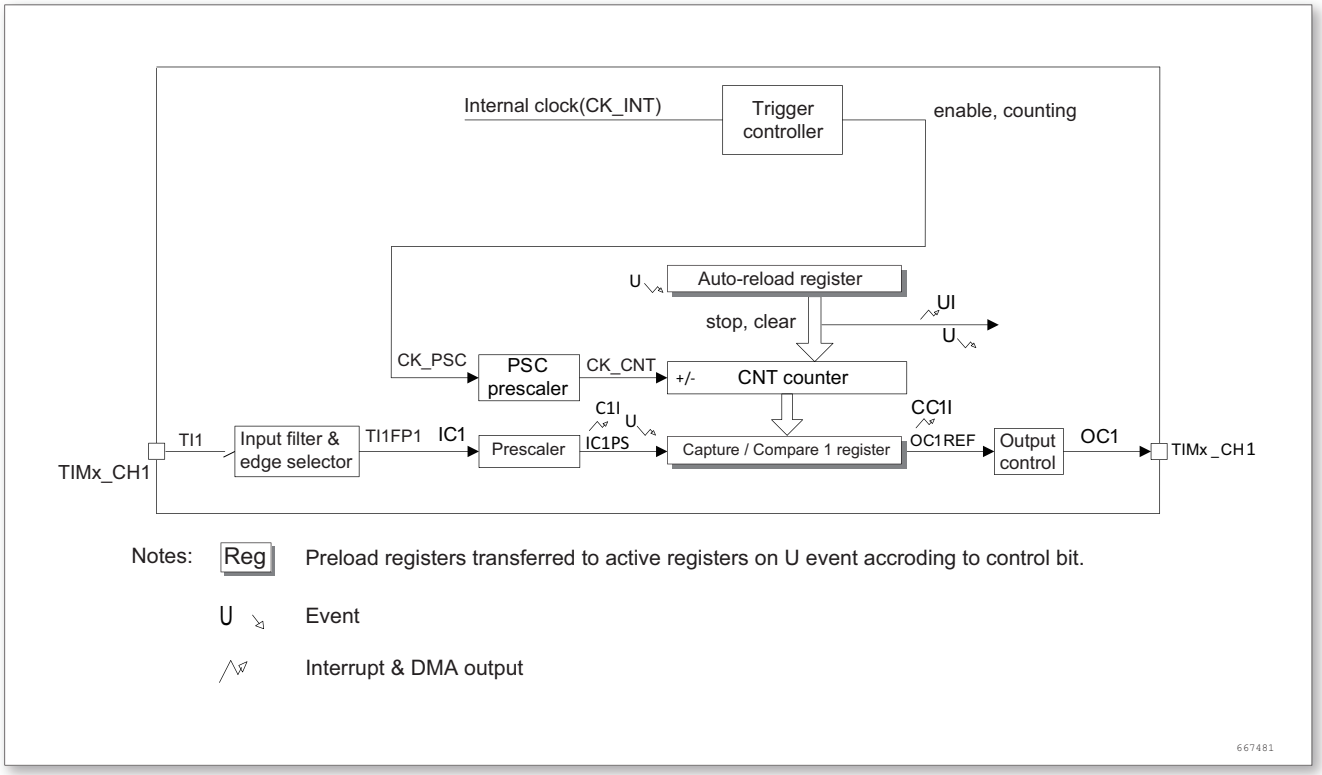

Figure 169. Block Diagram of basic timer

14.3 TIM14 Functional description

14.3.1 Time-base unit

The main block of the programmable basic timer is a 16-bit counter with its related auto-reload register. The counter can count up. The counter clock can be divided by a prescaler.The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running. The time-base unit includes:

- Counter register (TIMx_CNT)
- Prescaler register (TIMx_PSC)
- Auto-reload register (TIMx_ARR)

The auto-reload register is preloaded. The preload register is accessed each time an attempt is made to write or read the auto-reload register. The contents of the preload register are transferred into the shadow register permanently or at each update event UEV, depending on the auto-reload preload enable bit (ARPE) in the TIM14_CR1 register. The update event is sent when the counter reaches the overflow value and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in detail for each configuration.

The counter is clocked by the prescaler output CK_CNT, which is enabled only when the counter enable bit (CEN) in TIM14_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note: The actual counter enable signal CNT_EN is set 1 clock cycle after CEN.

Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as the TIMx_PSC control register is buffered. The new prescaler ratio is taken into account at the next update event.

The following figures give some examples of the counter behavior when the prescaler ratio is changed on the fly.

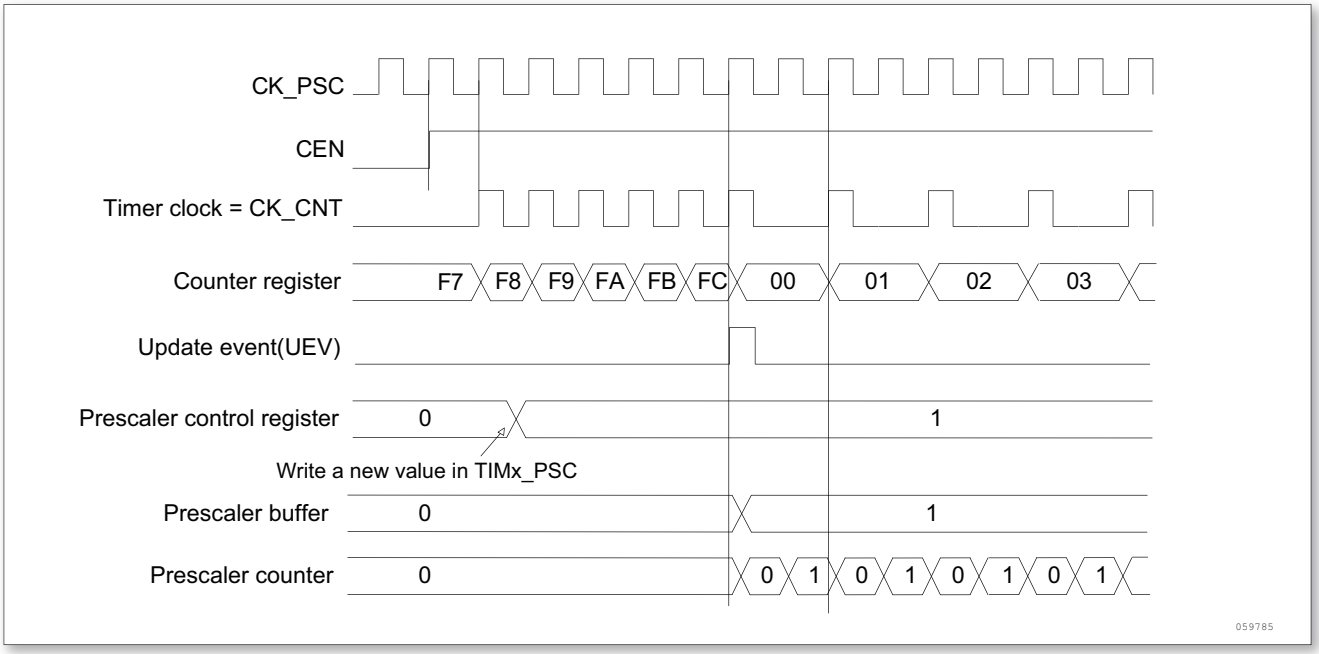

Figure 170. Counter Timing Diagram with Prescaler Division Change from 1 to 2

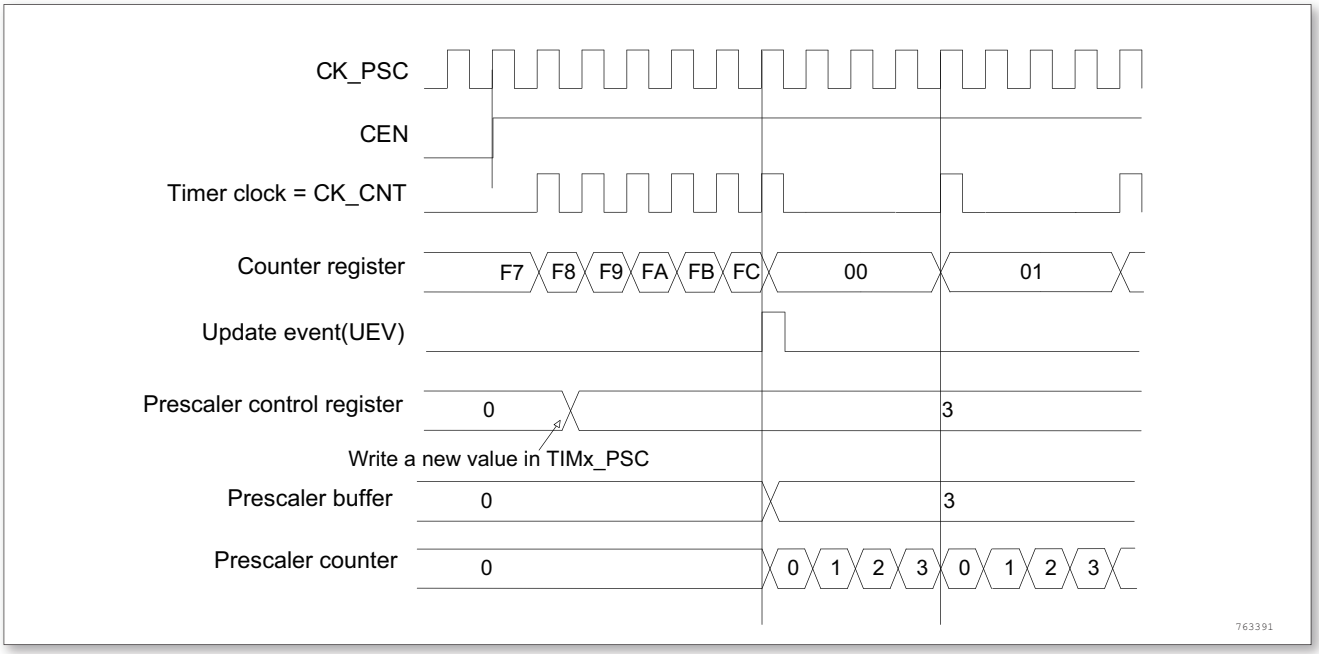

Figure 171. Counter Timing Diagram with Prescaler Division Change from 1 to 4

14.3.2 Counter modes

Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIM14_ARR register), then restarts from 0 and generates a counter overflow event.

Setting the UG bit in the TIM14_EGR register also generates an updateevent.

The UEV event can be disabled by software by setting the UDIS bit in the TIM14_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIM14_CR1 register is set, setting the UG bit generates an update event UEV but withoutsetting the UIF flag (thus no interrupt is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIM14_SR register) is set (depending on the URS bit):

- The auto-reload shadow register is updated with the preload value (TIM14_ARR).
- The buffer of the prescaler is reloaded with the preload value (content of the TIM14_PSC register).

The following figures show some examples of the counter behavior for different clock frequencies when TIM14_ARR=0x36.

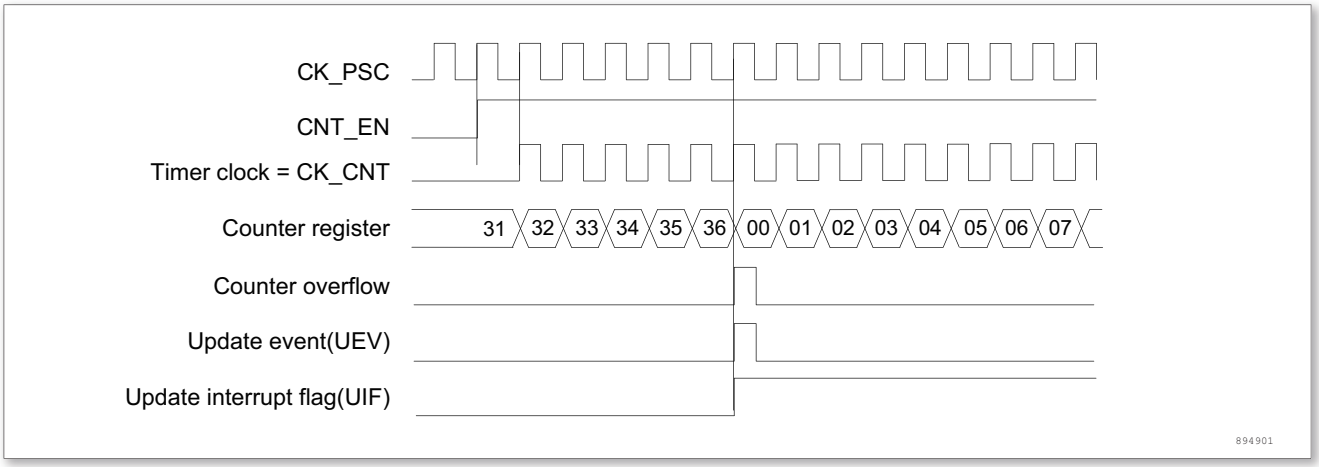

Figure 172. Counter Timing Diagram, Internal Clock Divided by 1

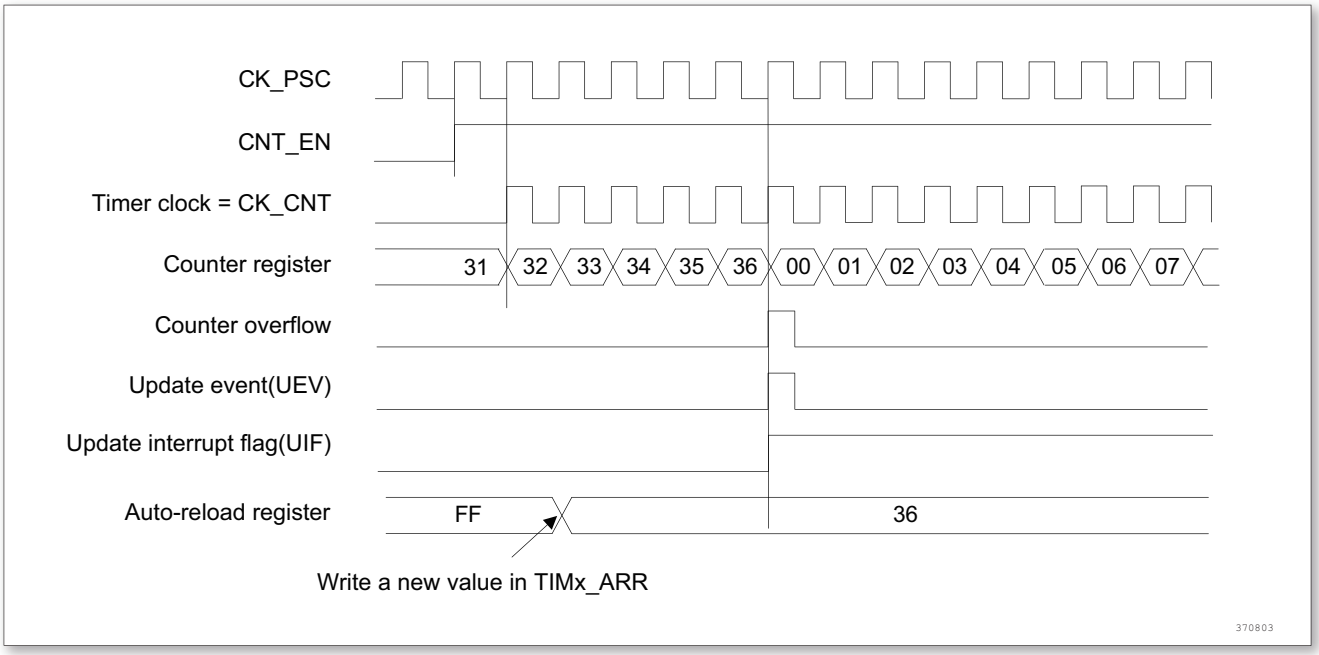

Figure 176. Counter Timing Diagram, Update Event When ARPE=0 (TIM14_ARR Not Preloaded)

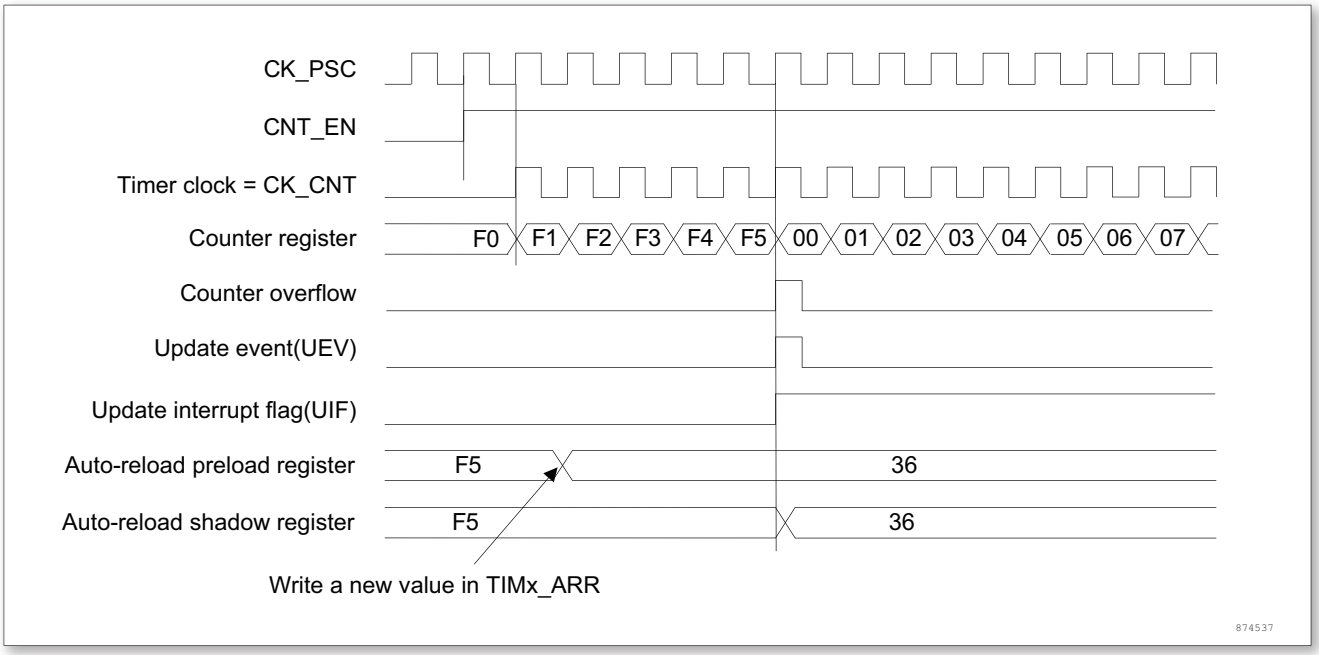

Figure 177. Counter Timing Diagram, Update Event When ARPE=1 (TIM14_ARR Preloaded)

14.3.3 Repetition counter

Time-base unit describes how the update event (UEV) is generated with respect to the counter overflows. It is actually generated only when the repetition counter has reached zero, which is very useful to generate PWM signal.

This means that data are transferred from the preload registers to the shadow registers (TIMx_ARR auto-reload register, TIMx_PSC prescaler register, but also TIMx_CCRx capture/compare registers in compare mode) every N counter overflows. N represents the value in TIMx_RCR repetition counter register, which diminishs in case of any following condition:

- At each counter overflow in upcounting mode

The repetition counter is an auto-reload type; the repetition rate is maintained as defined by the TIMx_RCR register value. When the update event is generated by software (by setting the UG bit in TIMx_EGR register) or by hardware through the slave mode controller, it occurs immediately whatever the value of the repetition counter is and the repetition counter is reloaded with the content of the TIMx_RCR register.

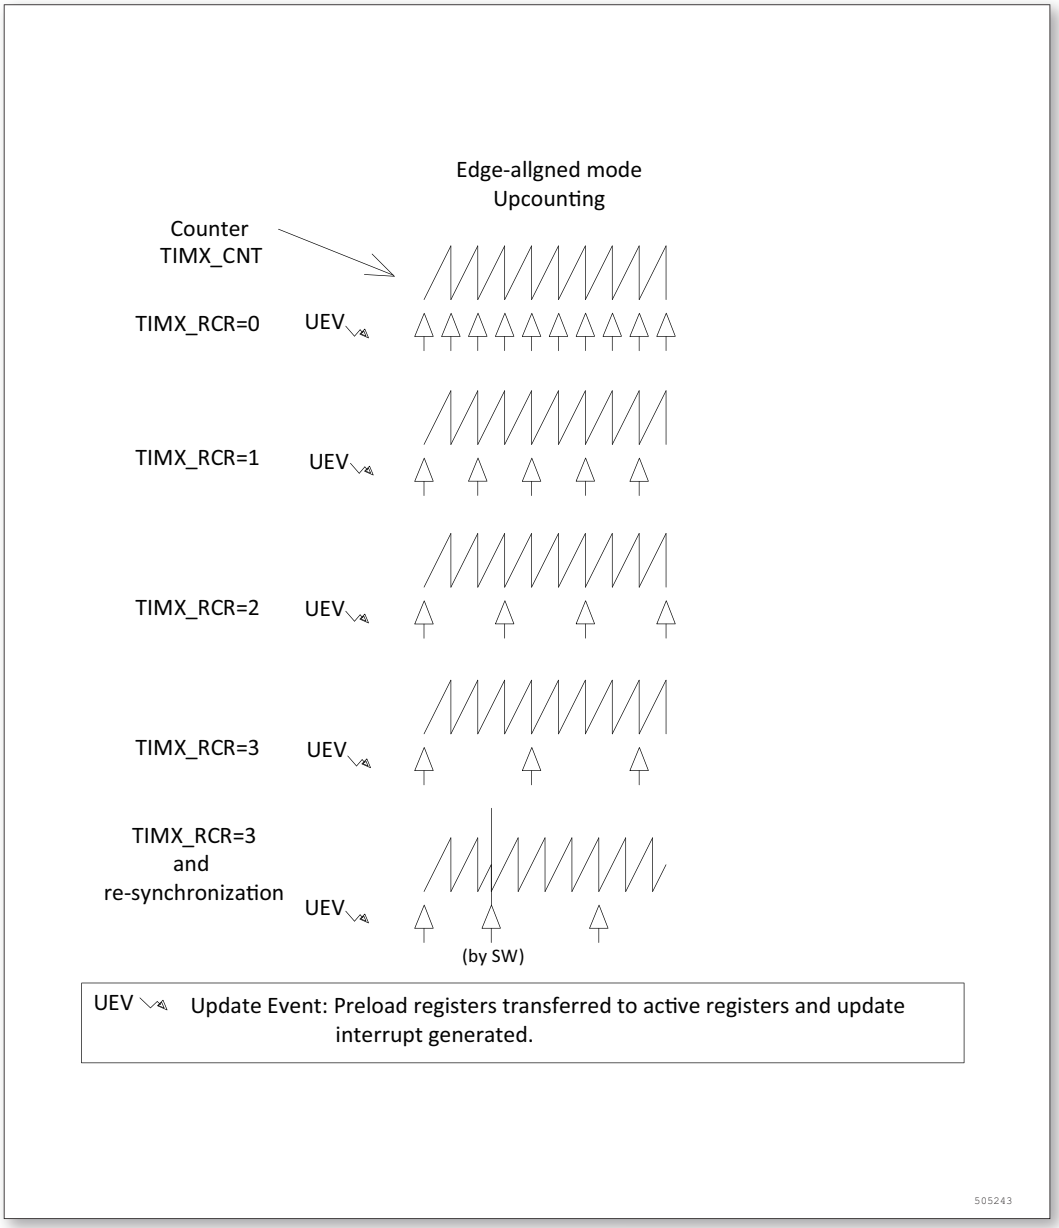

Figure 178. Example of Update Rates in Different Modes and Different TIMx_PCR Register Settings

14.3.4 Clock source

The counter clock is provided by the Internal clock (CK_INT) source.

The CEN (in the TIM14_CR1 register) and UG bits (in the TIM14_EGR register) are actual control bits and can be changed only by software (except for UG that remains cleared

automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock CK_INT.

The following figure shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

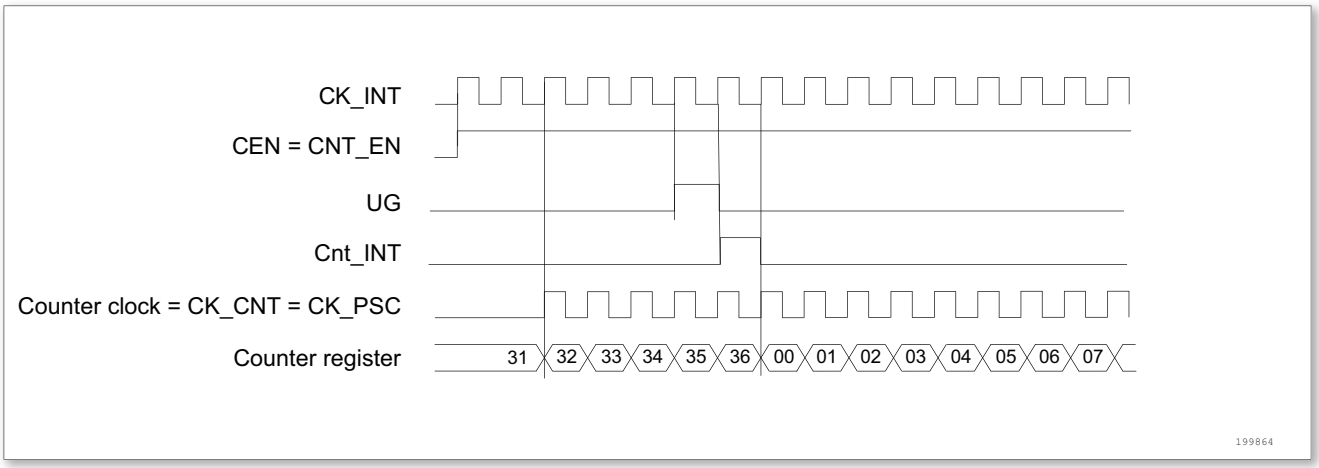

Figure 179. Control Circuit in Normal Mode, Internal Clock Divided By 1

14.3.5 Capture/compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), an input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control).

The following figures show a capture/compare channel. The input stage samples the corresponding TIx input to generate a filtered signal TIxF. Then, an edge detector with polarity selection generates a signal (TIxFPx) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).

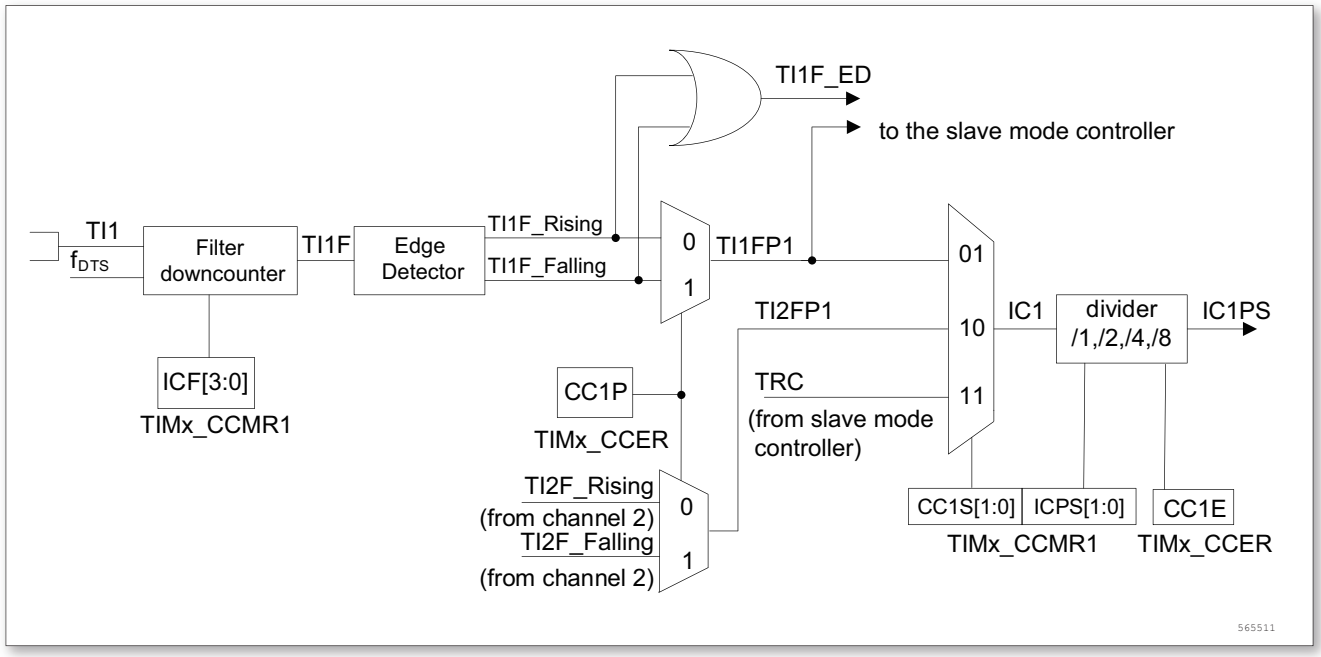

Figure 180. Capture/Compare Channel (Example: Channel 1 Input Stage)

The output stage generates an intermediate waveform which is then used for reference: OCxREF (active high). The polarity acts at the end of the chain.The output stage generates an intermediate waveform which is then used for reference: OCxREF (active high). The polarity acts at the end of the chain.

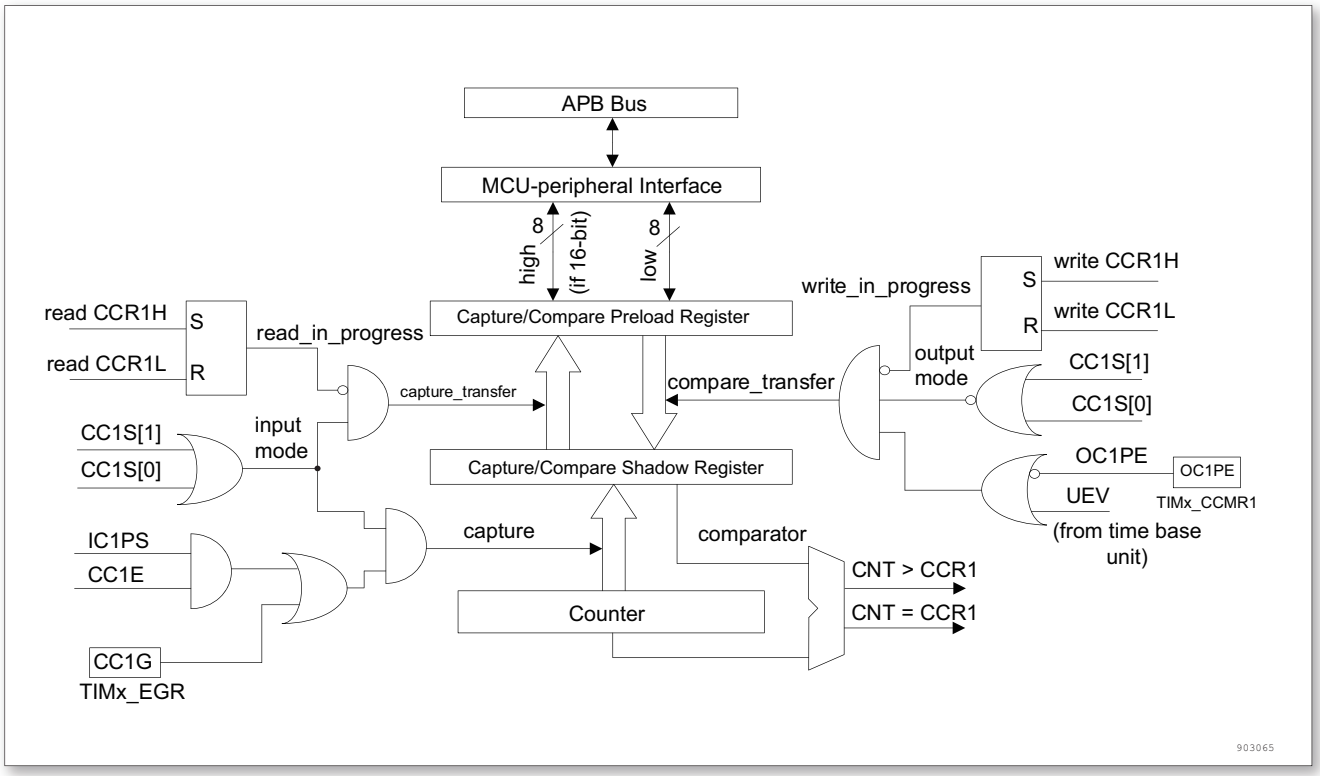

Figure 181. Capture/Compare Channel 1 Main Circuit

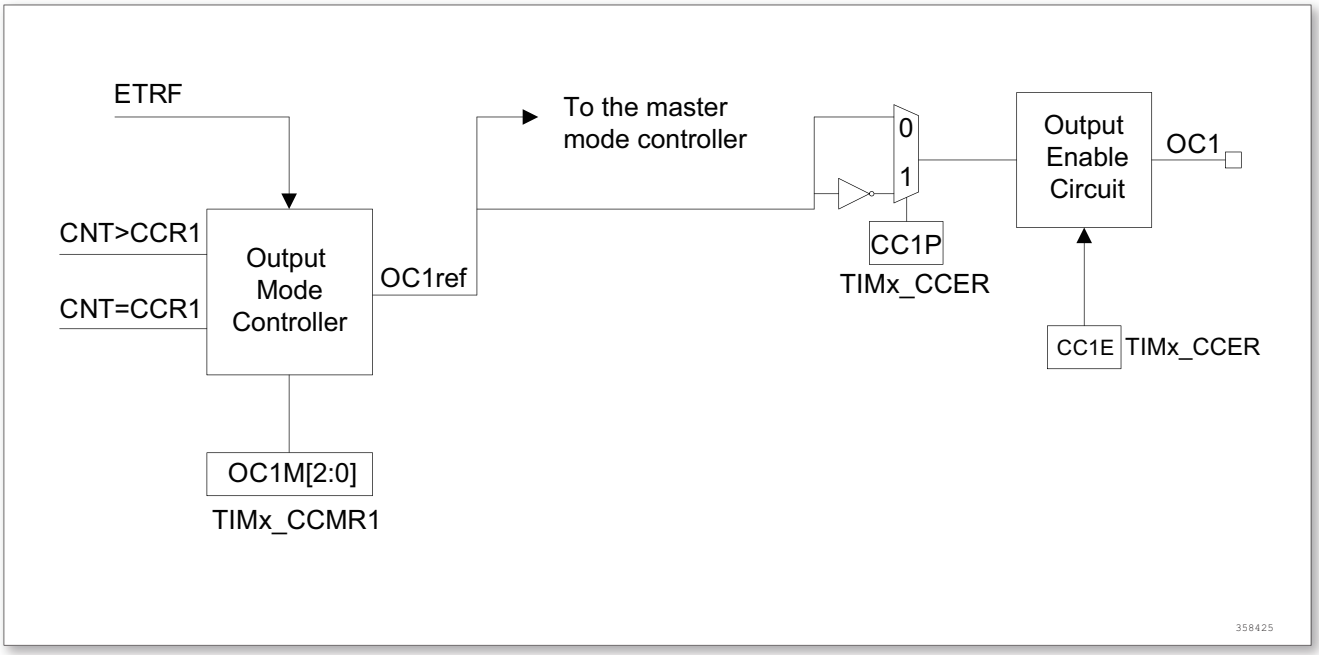

Figure 182. Output Stage of Capture/Compare Channel (Channel 1)

The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register. In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

14.3.6 Input capture mode

In Input capture mode, the Capture/Compare Registers (TIM14_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCXIF flag (TIM14_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxOF (TIM14_SR register) is set. CCxIF can be cleared by software by writing it to '0' or by reading the captured data stored in the TIM14_CCRx register. CCxOF is cleared when written to '0'.

The following example shows how to capture the counter value in TIM14_CCR1 when TI1 input rises. To do this, use the following procedure:

1. Select the active input: TIM14_CCR1 must be linked to the TI1 input, so write the CC1S bits to 01 in the TIM14_CCR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIM14_CCR1 register becomes read-only.
2. Program the needed input filter duration with respect to the signal connected to the timer (by programming ICxF bits in the TIM14_CCMRx register if the input is a TIx input). Let's imagine that, when toggling, the input signal is not stable during at must five internal clock cycles. We must program a filter bandwidth longer than these five clock cycles. We can validate a transition on TI1 when 8 consecutive samples with the new level have been detected (sampled at f_{DTS} frequency). Then write IC1F bits to 0011 in the TIM14_CCMR1 register.
3. Select the edge of the active transition on the TI1 channel by writing CC1P bit and CC1NP bit to 0 in the TIM14_CCER register (rising edge).
4. Configure the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to '00' in the TIM14_CCMR1 register).
5. Enable capture from the counter into the capture register by setting the CC1E bit in the TIM14_CCER register to '1'.
6. If needed, enable the related interrupt request by setting the CC1IE bit in the TIM14_DIER register, and/or the DMA request by setting the CC1DE bit in the TIM14_DIER register.

When an input capture occurs:

- The TIM14_CCR1 register gets the value of the counter on the active transition. CC1IF flag is set (interrupt flag). CC1IF is not cleared if at least two consecutive captures occurred. CC1OF is also set to 1.
- An interrupt is generated depending on the CC1IE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which could happen after reading the flag and before reading the data.

Note: IC (input compare) interrupt DMA request can be generated by software by setting the corre-

sponding CCxG bit in the TIM14_EGR register.

14.3.7 Forced output mode

In output mode (CCxS bits = 00 in the TIM14_CCMRx register), each output compare signal (OCxREF and then OCx) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (OCxREF/OCx) to its active level, the user just needs to write 101 in the OCxM bits in the corresponding TIM14_CCMRx register. Thus OCxREF is forced high (OCxREF is always active high) and OCx get opposite value to CCxP polarity bit.

For example: CCxP=0 (OCx active high) => OCx is forced to high level. OCxREF signal can be forced low by writing the OCxM bits to 100 in the TIM14_CCMRx register.

In this mode, the comparison between the TIM14_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt requests can be sent accordingly. This is described in the output compare mode section below.

14.3.8 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output compare function:

1. Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIM14_CCMRx register) and the output polarity (CCxP bit in the TIM14_CCER register). The output pin can keep its level (OCxM=000), be set active (OCxM=001), be set inactive (OCxM=010) or can toggle (OCxM=011) on match.
2. Sets a flag in the interrupt status register (CCxIF bit in the TIM14_SR register).
3. Generates an interrupt if the corresponding interrupt mask is set (CCXIE bit in the TIM14_DIER register).

The TIM14_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIM14_CCMRx register. In output compare mode, the update event UEV has no effect on OCxREF and OCx output. The timing precision is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

Procedure:

- Select the counter clock (internal, external, prescaler).
- Write the desired data in the TIM14_ARR and TIM14_CCRx registers.
- Set the CCxIE and/or CCxDE bits if an interrupt and/or a DMA request is to be generated.
- Select the output mode:
  - Write OCxM=011 to toggle OCx output pin when CNT matches CCRx
  - Write OCxPE = 0 to disable preload register

- Write CCxP = 0 to select active high polarity
- Write CCxE =1 to enable the output

• Enable the counter by setting the CEN bit in the TIM14_CR1 register.

The TIM14_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE=’0’, else TIM14_CCRx shadow register is updated only at the next update event UEV). An example is given in the following figure.

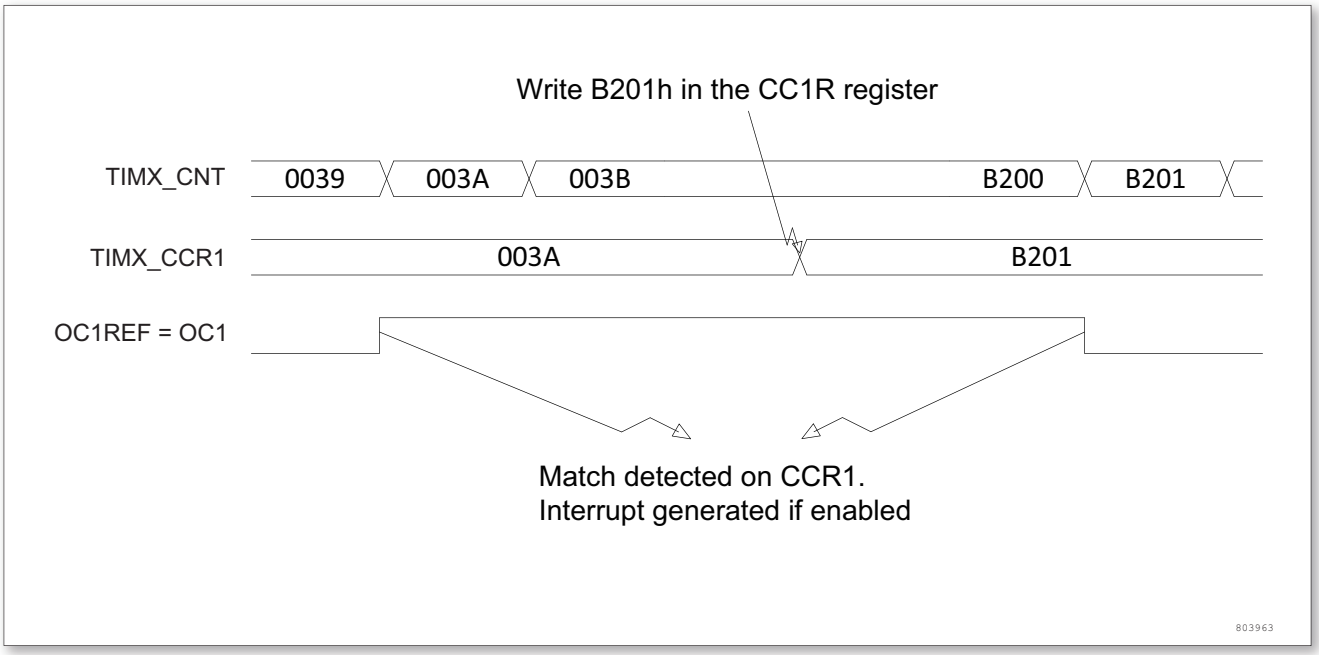

Figure 183. Output Compare Mode, Toggle on OC1

14.3.9 PWM mode

Pulse Width Modulation mode allows generating a signal with a frequency determined by the value of the TIM14_ARR register and a duty cycle determined by the value of the TIM14_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per OCx output) by writing ‘110’(PWM mode 1) or ‘111’(PWM mode 2) in the OCxM bits in the TIM14_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIM14_CCMRx register, and eventually the auto-reload preload register (in upcounting mode) by setting the ARPE bit in the TIM14_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, the user must initialize all the registers by setting the UG bit in the TIM14_EGR register.

OCx polarity is software programmable using the CCxP bit in the TIM14_CCER register. It can be programmed as high or low. OCx output is enabled by the CCxE bit in the TIM14_CCER register. Refer to the TIM14_CCERx register description for more details.

In PWM mode (1 or 2), TIM14_CNT and TIM14_CCRx are always compared to determine whether TIM14_CNT ≤ TIMx_CCRx.

The upcounting timer is only able to generate PWM in edge-aligned mode.

PWM edge-aligned mode

In the following example, we consider PWM mode 1. The reference PWM signal OCxREF is high as long as TIM14_CNT < TIM14_CCRx else it becomes low. If the compare value in TIM14_CCRx is greater than the auto-reload value (in TIM14_ARR) then OCxREF is held at ‘1. If the compare value is 0 then OCxREF is held at ‘0. The following figure shows some edge-aligned PWM waveforms in an example where TIM14_ARR=8.

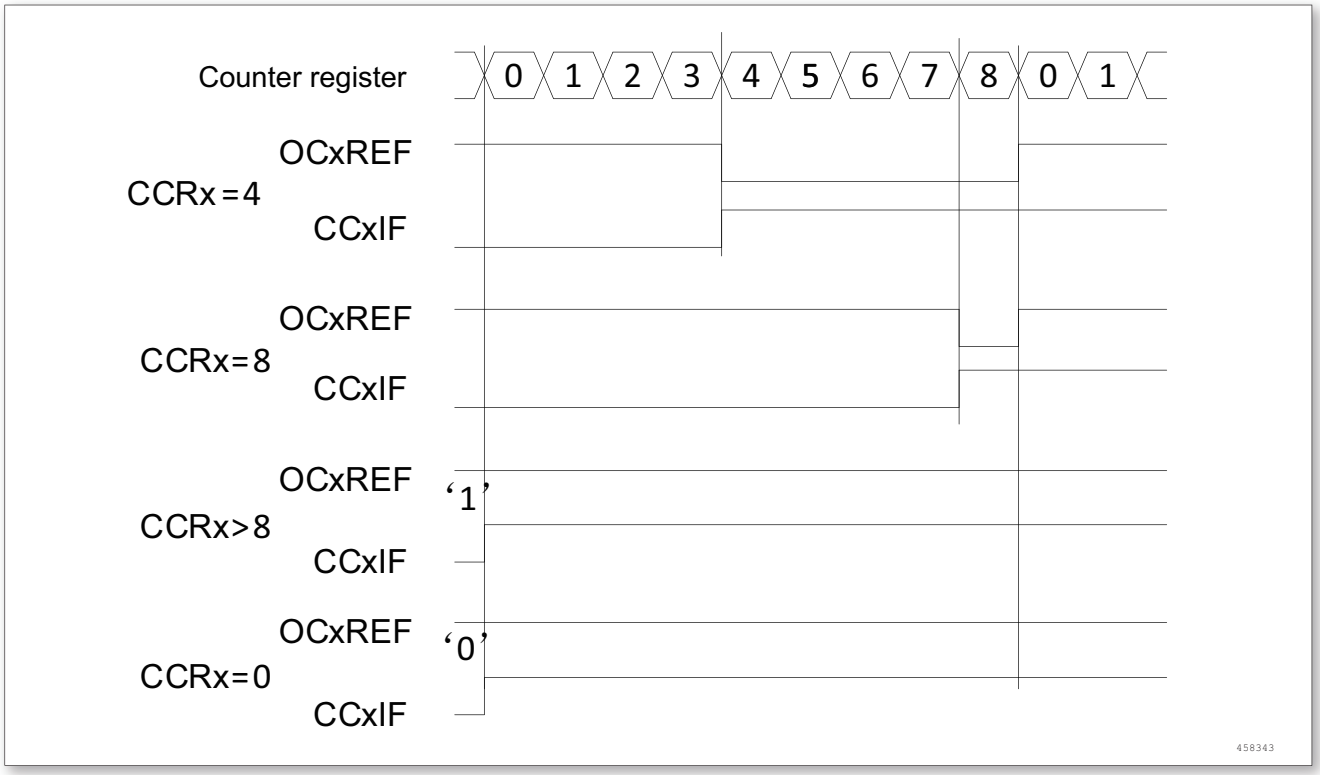

Figure 184. Edge-aligned PWM Waveforms (ARR=8)

14.3.10 Debug mode

When the microcontroller enters debug mode (Cortex™-M0 halted), the TIM14 counter either continues to work normally or stops, depending on DBG_TIMx_STOP configuration bit in DBG module.

If channel CC1 is configured as input: The current value of the counter is captured in TIM14_CCR1 register. The CC1IF flag is set, the corresponding interrupt is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.
0	UG	w	0x00	Update generation This bit can be set by software, it is automatically cleared by hardware. 0: No action 1: Reinitialize the counter and generates an update event. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected). The counter is cleared.

14.4.5 Capture/compare mode register 1(TIM14_CCMR1)

Offset address: 0x18

Reset value: 0x0000

The channels can be used in input (capture mode) or in output (compare mode). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode. For a given bit, OCxx describes its function when the channel is configured in output, ICxx describes its function when the channel is configured in input. So the user must take care that the same bit can have a different meaning for the input stage and for the output stage.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								Res.	OC1M			OC1PE	OC1FE	CC1S

								rw	rw	rw	rw	rw	rw	rw	rw

Output compare mode:

Bit	Field	Type	Reset	Description
15:7	Reserved			Reserved, always read as 0.
6: 4	OC1M	rw	0x00	Output compare 1 mode These bits define the behavior of the output reference signal OC1REF from which OC1 are derived. OC1REF is active high whereas OC1 active level depends on CC1P bit. 000: Frozen - The comparison between the output compare register TIM14_CCR1 and the counter TIM14_CNT has no effect on OC1REF 001: Set channel 1 to active level on match. OC1REF signal is forced high when the counter TIM14_CNT matches the capture/compare register 1 (TIM14_CCR1). 010: Set channel 1 to inactive level on match. OC1REF signal is forced low when the counter TIM14_CNT matches the capture/compare register 1 (TIM14_CCR1). 011: Toggle - OC1REF toggles when TIM14_CNT=TIM14_CCR1. 100: Force inactive level - OC1REF is forced low. 101: Force active level - OC1REF is forced high. 110: PWM mode 1 - Channel 1 is active as long as TIM14_CNT < TIM14_CCR1 else inactive. 111: PWM mode 2 - Channel 1 is inactive as long as TIM14_CNT < TIM14_CCR1 else active. In PWM mode 1 or 2, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from “frozen” mode to “PWM” mode.
3	OC1PE	rw	0x00	Output compare 1 preload enable 0: Preload register on TIM14_CCR1 disabled. TIM14_CCR1 can be written at anytime, the new value is taken in account immediately. 1: Preload register on TIM14_CCR1 enabled. Read/Write operations access the preload register. TIM14_CCR1 preload value is loaded in the active register at each update event. Note: The PWM mode can be used without validating the preload register only in one pulse mode (OPM bit set in TIM14_CR1 register). Else the behavior is not guaranteed.

Bit	Field	Type	Reset	Description
2	OC1FE	rw	0x00	Output compare 1 fast enable This bit is used to accelerate the effect of an event on the trigger in input on the CC output. 0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles. 1: An active edge on the trigger input acts like a compare match on CC1 output. Then, OC is set to the compare level independently from the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OCFE acts only if the channel is configured in PWM1 or PWM2 mode.
1: 0	CC1S	rw	0x00	Capture/Compare 1 selection This bit-field defines the direction of the channel (input/output) as well as the used input. 00: CC1 channel is configured as output 01: CC1 channel is configured as input, IC1 is mapped on TI1 10: Reserved 11: Reserved Note: CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIM14_CCER).

Input capture mode:

Bit	Field	Type	Reset	Description
15: 0	CCR1	rw	0x0000	Capture/Compare 1 value If CC1 channel is configured as output: CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value). It is loaded permanently if the preload feature is not selected in the TIM14_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs. The active capture/compare register contains the value to be compared to the counter TIM14_CNT and signaled on OC1 output. If CC1 channel is configured as input: CCR1 contains the counter value transferred by the last input capture 1 event (IC1).

15 Basic timer(TIM16/17)

Basic timer(TIM16/17)

15.1 TIM16/17 introduction

The basic timer TIM16/17 consists of a 16-bit auto-reload counter driven by a programmable prescaler. It has multiple purposes, including measuring pulse width (input capture) of input signal or generating output waveform (output compare and PWM).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The basic timer (TIM16/17) is completely independent, sharing no resource.

15.2 Main features

- 16-bit up auto-reload register
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65536.
- 1 independent channel for:
  - Input capture
  - Output compare
  - PWM generation (edge-aligned mode)
  - One-pulse mode output
- Complementary output of programmable dead time
- Repetition counter to update the timer registers only after a given number of cycles of the counter
- Break input to put the timer’s output signals in reset state or in a known state
- Interrupt/DMA generation on the following events:
  - Update: counter overflow
  - Input capture
  - Output compare
  - Break signal input

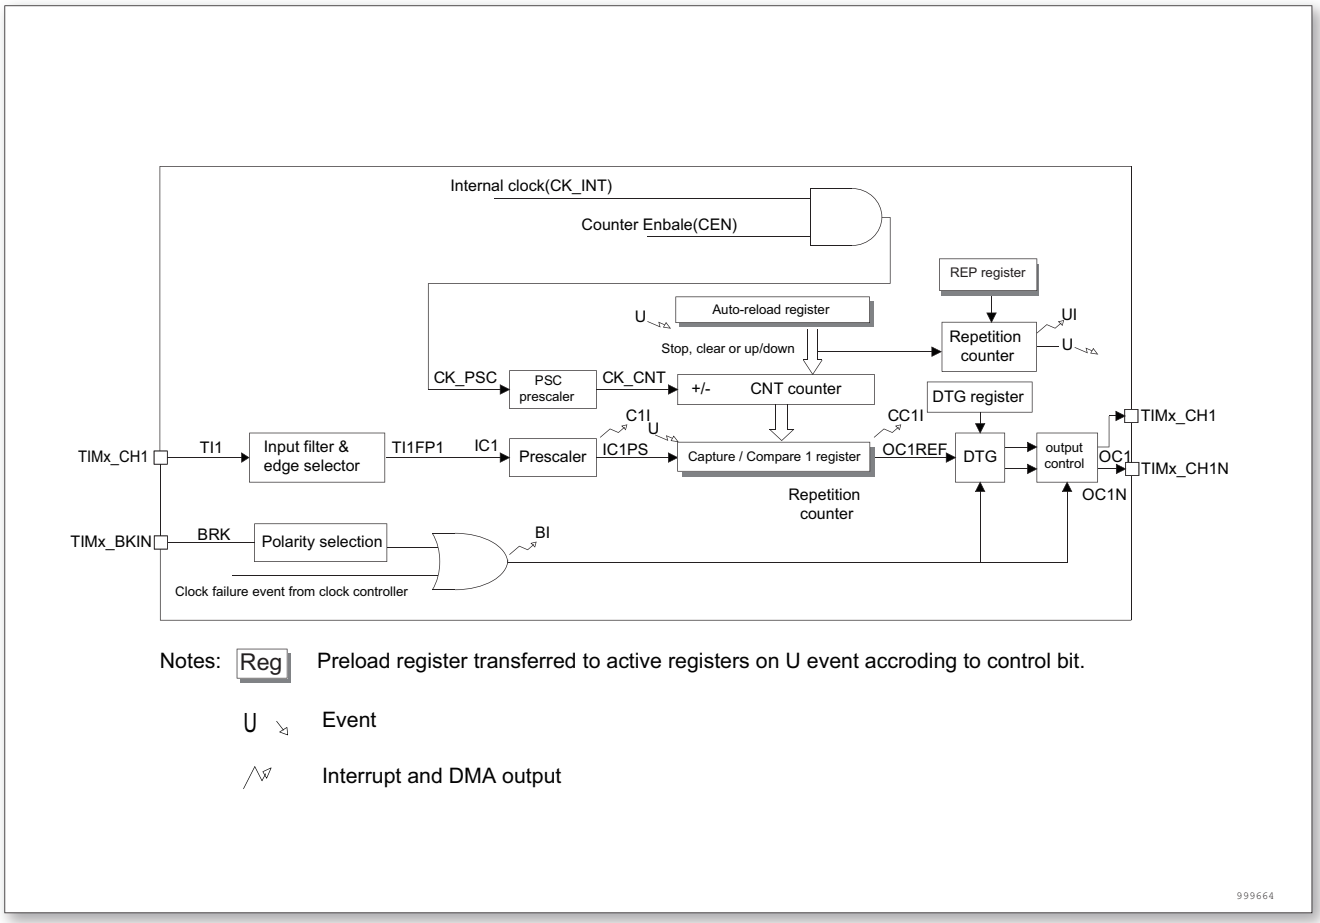

Figure 185. Basic Timers TIM16 and TIM17 Block Diagram

15.3 Functional description

15.3.1 Time-base unit

The main block of the programmable timer is a 16-bit upcounter with its related auto-reload register. The counter can count up, down or both up and down. The counter clock can be divided by a prescaler. The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running. The time-base unit includes:

- Counter register (TIMx_CNT)
- Prescaler register (TIMx_PSC)
- Auto-reload register (TIMx_ARR)
- Repetition counter register (TIMx_RCR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter overflow (or underflow when downcounting) and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in details for each configuration.

The counter is clocked by the prescaler output CK_CNT, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note: The actual counter enable signal is set 1 clock cycle after CEN.

Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

The following figure gives some examples of the counter behavior when the prescaler ratio is changed on the fly:

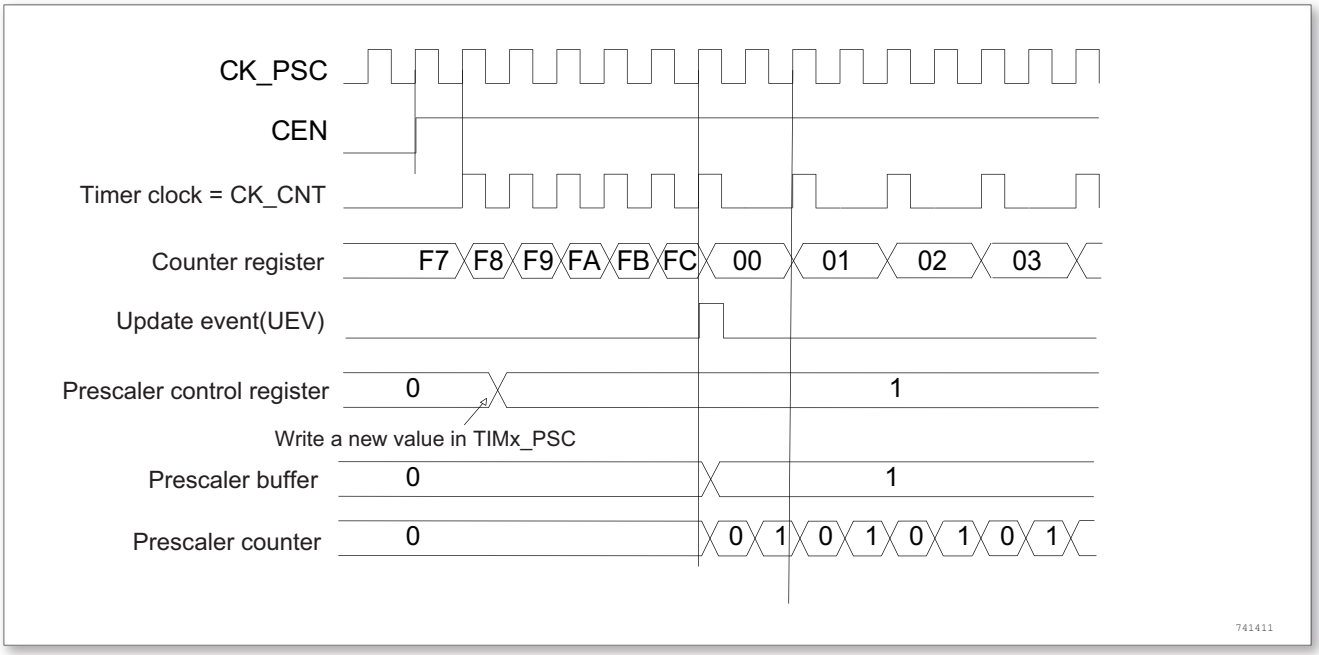

Figure 186. Counter Timing Diagram with Prescaler Division Change from 1 to 2

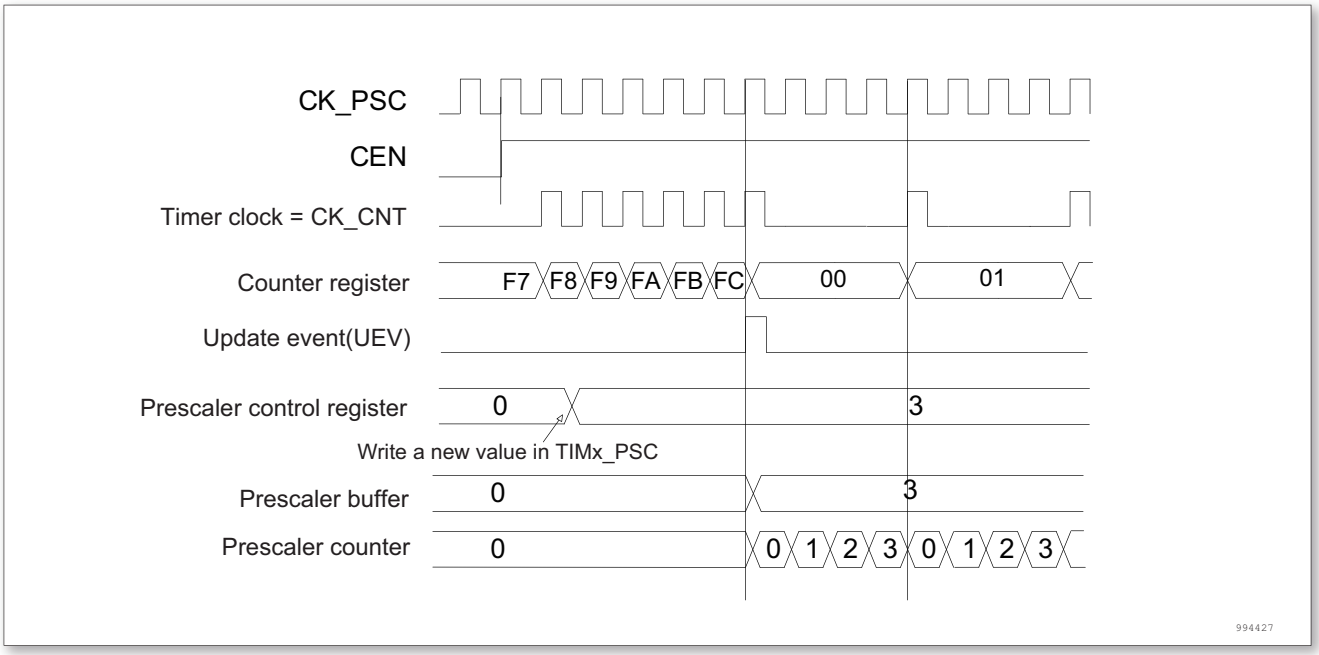

Figure 187. Counter Timing Diagram with Prescaler Division Change from 1 to 4

15.3.2 Counting unit

Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

If the repetition counter is used, the update event (UEV) is generated after upcounting is repeated for the number of times programmed in the repetition counter register (TIMx_RCR). Else, the update event is generated at each counter overflow. An update event can be generated at each counter overflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller).

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event. When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit).

- The repetition counter is reloaded with the content of TIMx_RCR register.
- The auto-reload shadow register is updated with the preload value (TIMx_ARR).
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

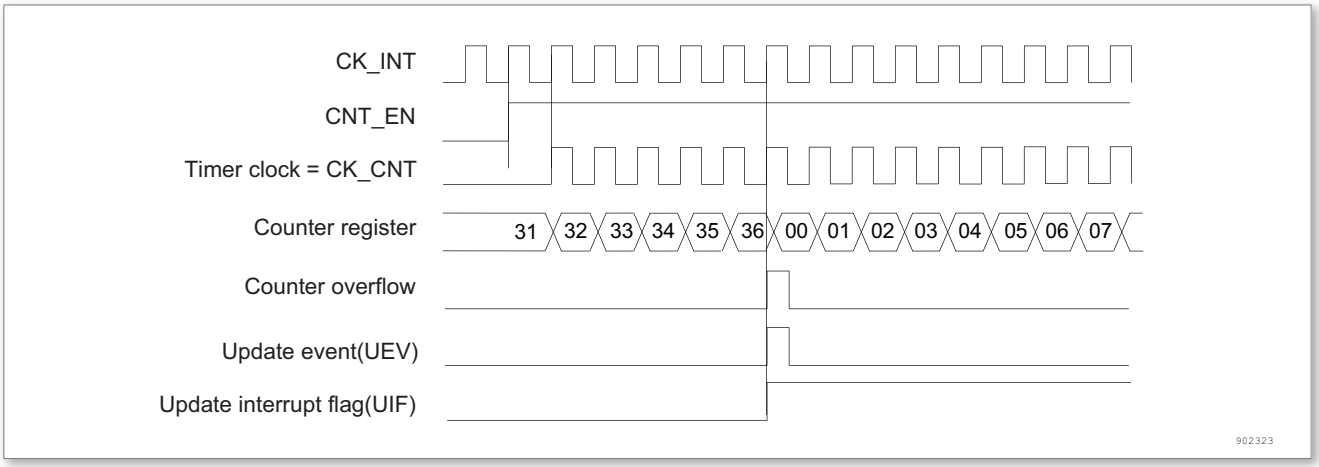

Figure 188. Counter Timing Diagram, Internal Clock Divided by 1

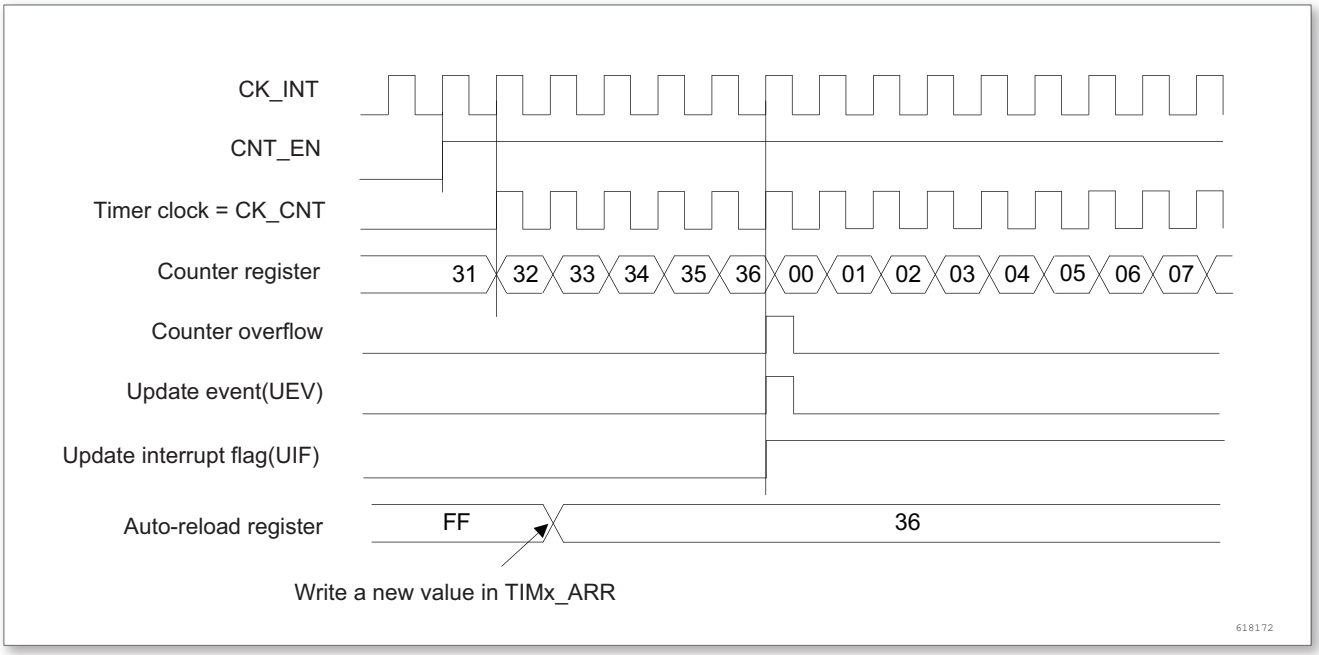

Figure 192. Counter Timing Diagram, Update Event When APRE=0 (TIMx_ARR Not Preloaded)

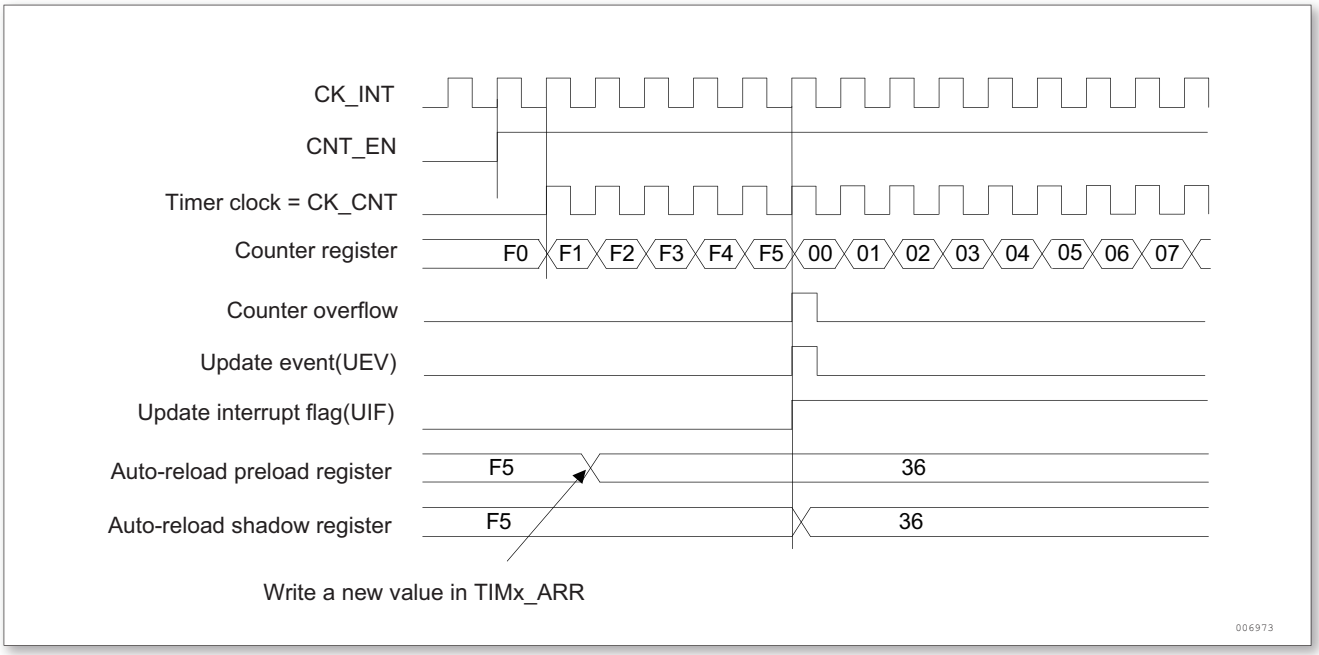

Figure 193. Counter Timing Diagram, Update Event When APRE=1 (TIMx_ARR Preloaded)

15.3.3 Repetition counter

Time-base unit describes how the update event (UEV) is generated with respect to the counter overflows. It is actually generated only when the repetition counter has reached zero, which is very useful to generate PWM signal.

This means that data are transferred from the preload registers to the shadow registers (TIMx_ARR auto-reload register, TIMx_PSC prescaler register, but also TIMx_CCRx capture/compare registers in compare mode) every N counter overflow, where N is the value in the TIMx_RCR repetition counter register.

The repetition counter is decremented:

At each counter overflow in upcounting mode, the repetition counter is auto-reloaded; the repetition rate is maintained as defined by the TIMx_RCR register value. When the update event is generated by software (by setting the UG bit in TIMx_EGR register) or by hardware through the slave mode controller, it occurs immediately whatever the value of the repetition counter is and the repetition counter is reloaded with the content of the TIMx_RCR register.

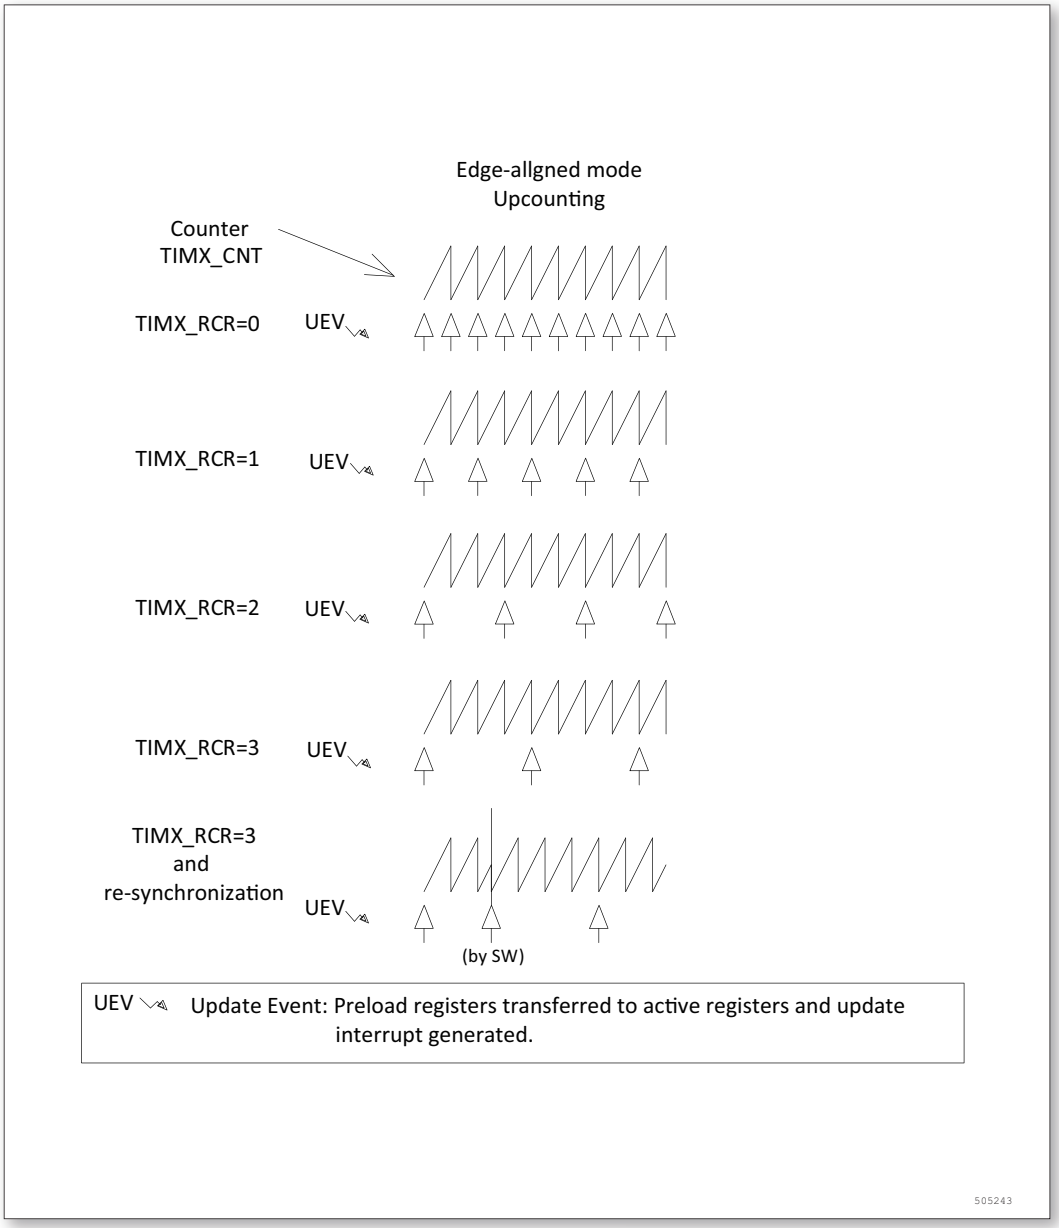

Figure 194. Example of Update Rates in Different Modes and Different TIMx_PCR Register Settings

15.3.4 Clock source

The counter clock can be provided by the following clock sources:

- Internal clock(CK_INT).

Internal clock source(CK_INT)

If the slave mode controller is disabled (SMS=000 in the TIMx_SMCR register), then the CEN, DIR (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock CK_INT.

The following figure shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

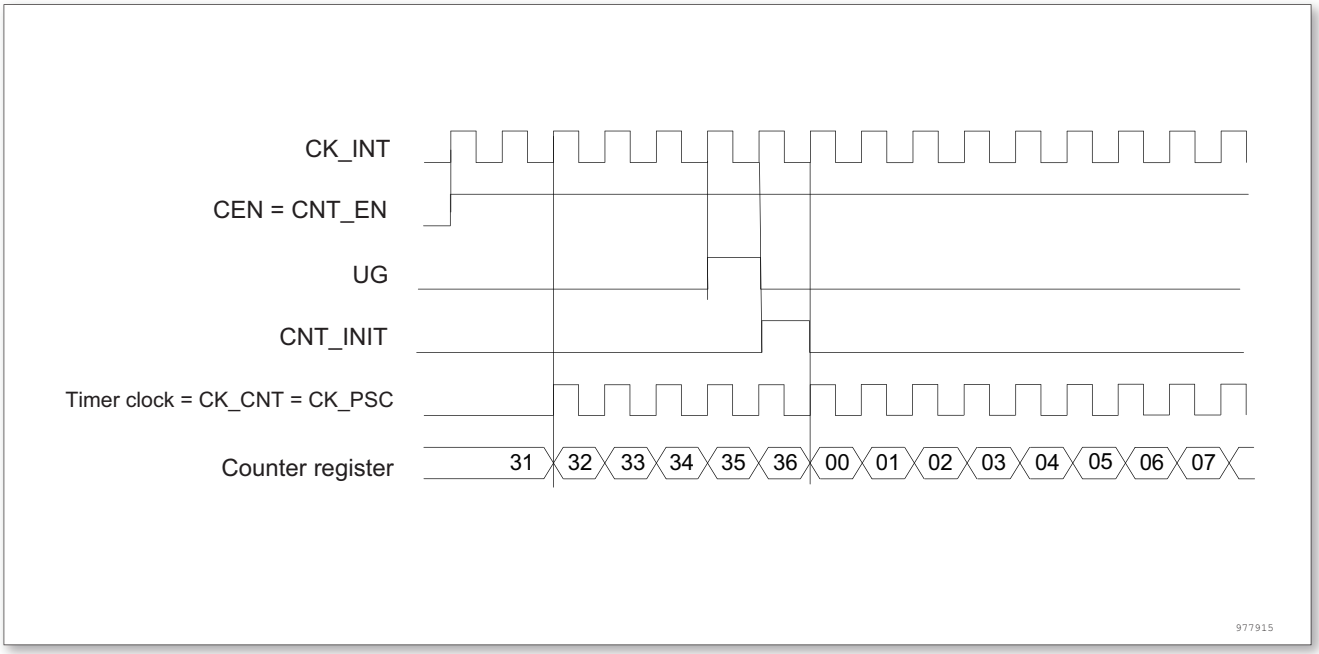

Figure 195. Control Circuit in Normal Mode, Internal Clock Divided By 1

15.3.5 Capture/compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), an input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control). The following figures give an overview of one Capture/Compare channel.

The input stage samples the corresponding TIx input to generate a filtered signal TIxF. Then, an edge detector with polarity selection generates a signal (TIxFPx) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).

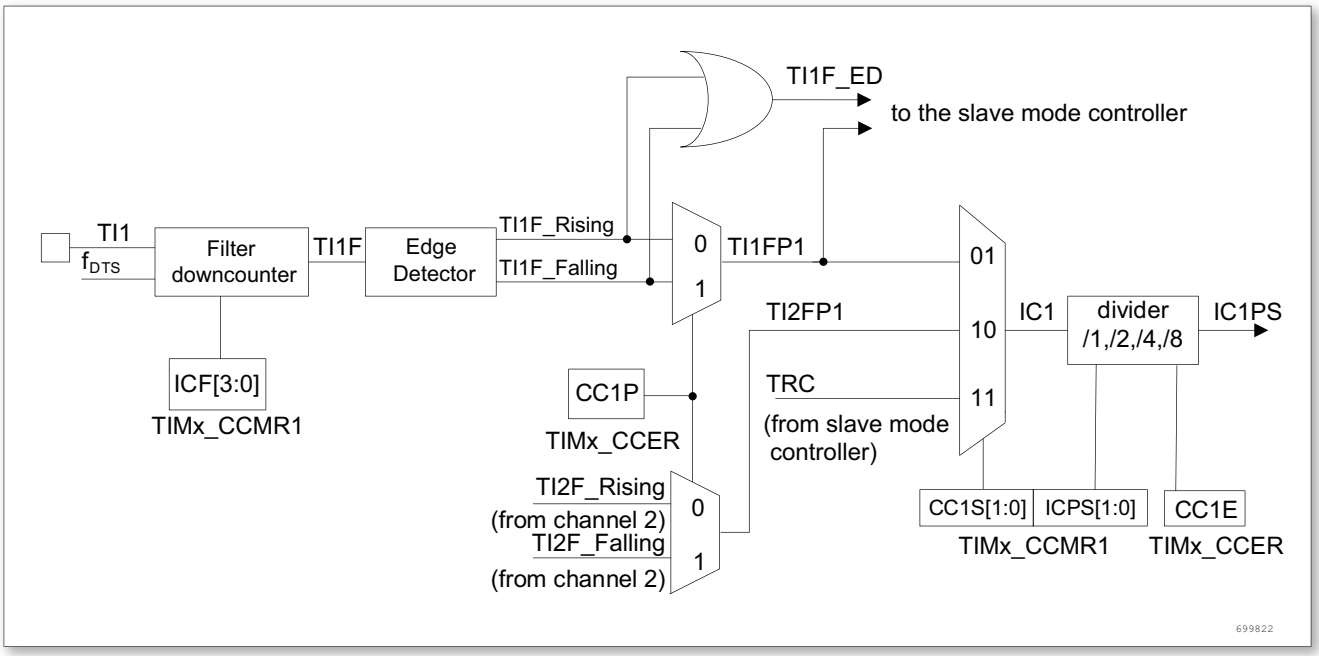

Figure 196. Capture/Compare Channel (Example: Channel 1 Input Stage)

The output stage generates an intermediate waveform which is then used for reference: OCxREF (active high). The polarity acts at the end of the chain.

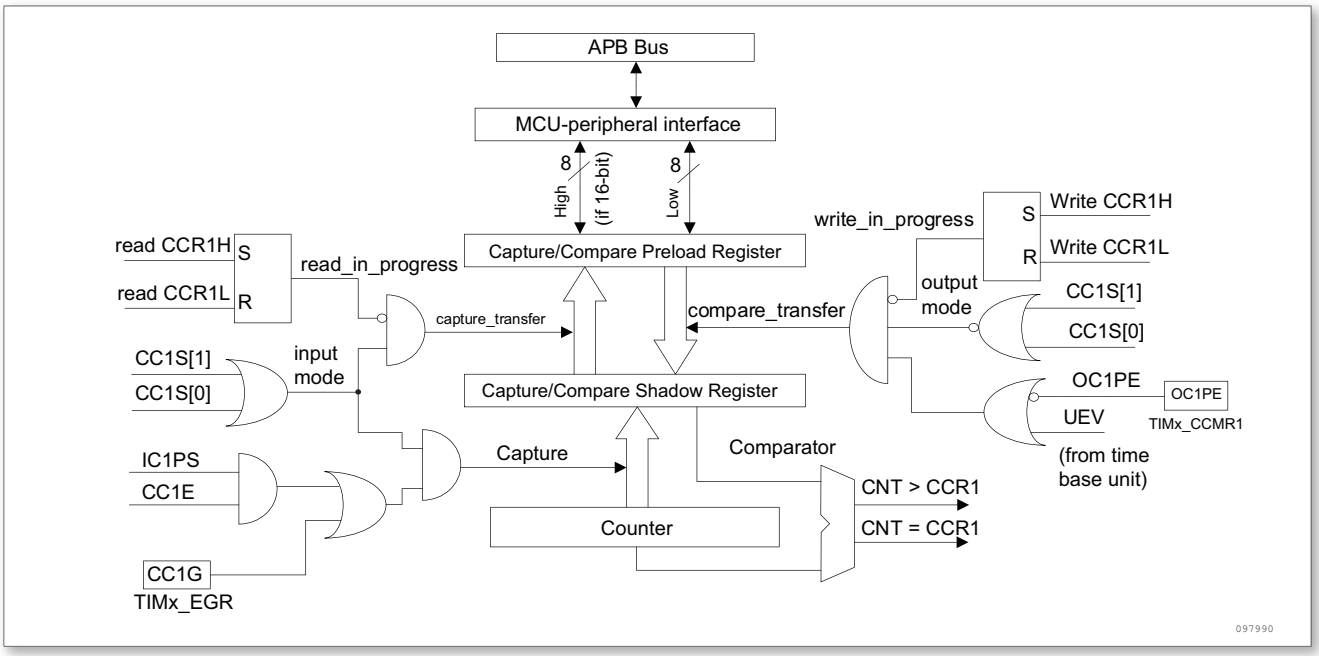

Figure 197. Capture/Compare Channel 1 Main Circuit

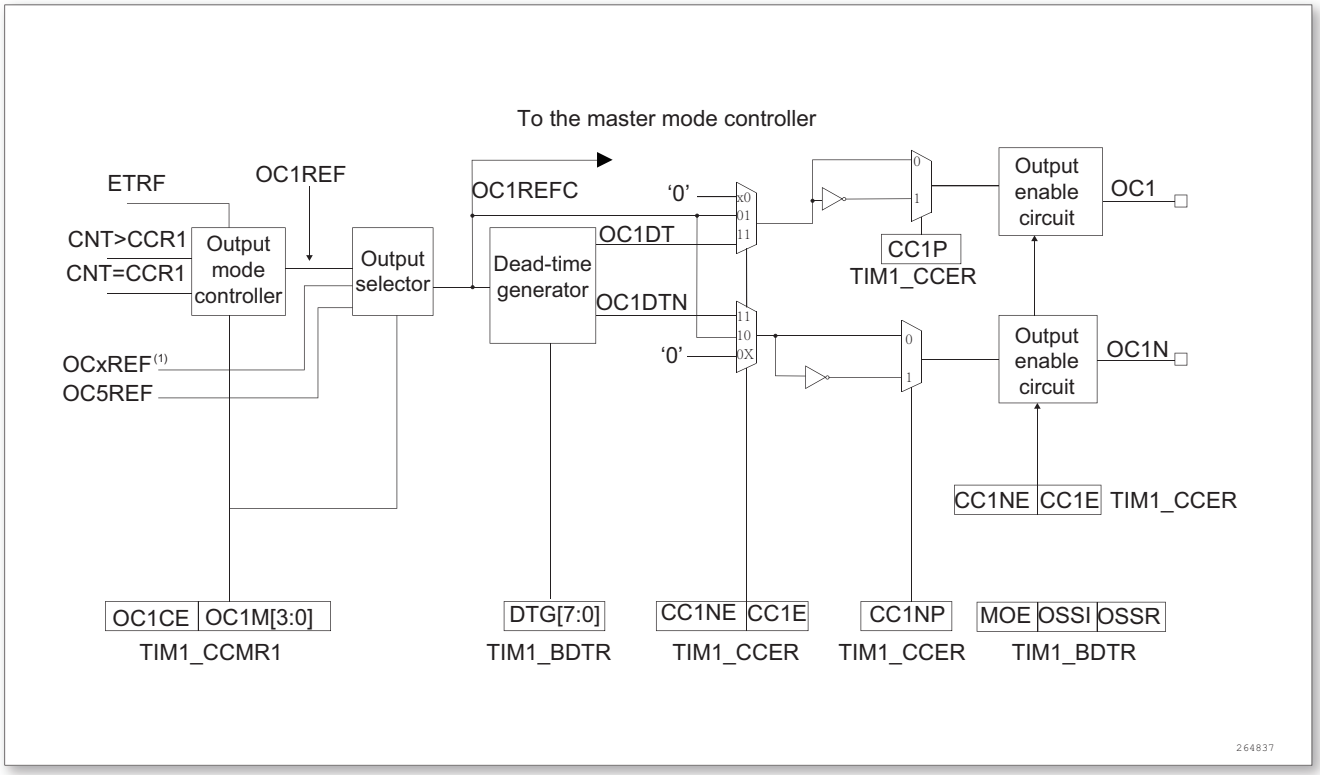

Figure 198. Output Stage of Capture/Compare Channel (Channel 1)

The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register. In capture mode, captures are actually done in the shadow register, which is copied into the preload register. In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

15.3.6 Input capture mode

In Input capture mode, the Capture/Compare Registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCxIF flag (TIMx_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxOF (TIMx_SR register) is set, CCxIF can be cleared by software by writing it to 0 or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when written to 0.

The following example shows how to capture the counter value in TIMx_CCR1 when TI1 input rises.

Procedures:

- Select the active input: TIMx_CCR1 must be linked to the TI1 input, so write the CC1S bits to 01 in the TIMx_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TM1_CCR1 register becomes read-only.
- Program the needed input filter duration with respect to the signal connected to the timer (by programming ICxF bits in the TIMx_CCMRx register if the input is a TIx input). Let’s imagine that, when toggling, the input signal is not stable during at must five

internal clock cycles. We must program a filter bandwidth longer than these five clock cycles. We can validate a transition on TI1 when 8 consecutive samples with the new level have been detected (sampled at fDTS frequency). Then write IC1F bits to 0011 in the TIMx_CCMR1 register.

- Select the edge of the active transition on the TI1 channel by writing CC1P bit to 0 in the TIMx_CCER register (rising edge in this case).
- Configure the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to '00' in the TIMx_CCMR1 register).
- Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx_CCER register to '1'.
- If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx_DIER register.

When an input capture occurs:

- The TIMx_CCR1 register gets the value of the counter on the active transition.
- C1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the CC1IF flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which could happen after reading the flag and before reading the data.

Note: IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx_EGR register.

15.3.7 Forced output mode

In output mode (CCxS bits = 00 in the TIMx_CCMRx register), each output compare signal (OCxREF and then OCx) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (OCxREF/OCx) to its active level, the user just needs to write 101 in the OCxM bits in the corresponding TIMx_CCMRx register. Thus OCxREF is forced high (OCxREF is always active high) and OCx get opposite value to CCxP polarity bit.

For example: CCxP=0 (OCx active high) => OCx is forced to high level.

The OCxREF signal can be forced low by writing the OCxM bits to 100 in the TIMx_CCMRx register.

Anyway, in this mode, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the output compare mode section below.

15.3.8 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP bit in the TIMx_CCER register). The output pin can keep its level (OCxM=000), be set active (OCxM=001), be set inactive (OCxM=010) or can toggle (OCxM=011) on match.
- Sets a flag in the interrupt status register (CCxIF bit in the TIMx_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCxIE bit in the TIMx_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx_DIER register, CCDS bit in the TIMx_CR2 register for the DMA request selection).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register. In output compare mode, the update event UEV has no effect on OCxREF and OCx output. The timing precision is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

Procedure:

- Select the counter clock (internal, external, prescaler).
- Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
- Set the CCxIE bit if an interrupt request is to be generated.
- Select the output mode:
  - Write OCxM=011 to toggle OCx output pin when CNT matches CCRx
  - Write OCxPE = 0 to disable preload register
  - Write CCxP = 0 to select active high polarity
  - Write CCxE = 1 to enable OCx
- Enable the counter by setting the CEN bit in the TIMx_CR1 register.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE=’0’, else TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in the following figure.

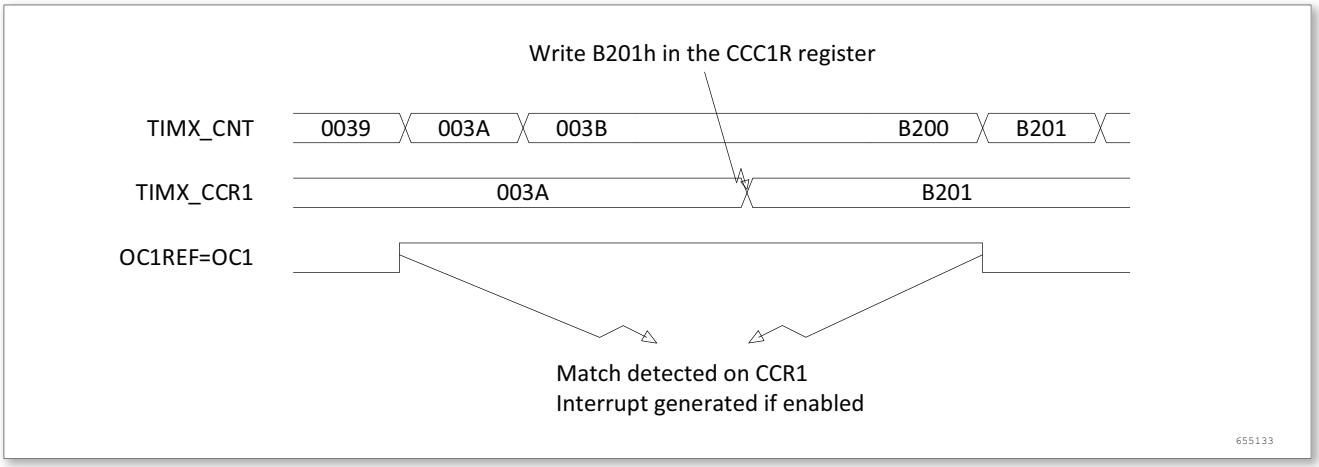

Figure 199. Output Compare Mode, Toggle on OC1

15.3.9 PWM mode

Pulse Width Modulation mode allows generating a signal with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per OCx output) by writing ‘110’ (PWM mode 1) or ‘111’ (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx_CCMRx register, and eventually the auto-reload preload register (in upcounting mode) by setting the ARPE bit in the TIMx_CR1 register. As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, the user must initialize all the registers by setting the UG bit in the TIMx_EGR register.

OCx polarity is software programmable using the CCxP bit in the TIMx_CCER register. It can be programmed as active high or active low. OCx output is enabled by CCxE, CCxNE, MOE, OSSI and OSSR bits (TIMx_CCER and TIMx_BDTR registers). Refer to the TIMx_CCER register description for more details.

In PWM mode (1 or 2), TIMx_CNT and TIMx_CCRx are always compared to determine whether TIMx_CCRx ≤TIMx_CNT or TIMx_CNT ≤TIMx_CCRx (depending on the direction of the counter). The timer is able to generate PWM in edge-aligned mode or center-aligned mode, depending on the CMS bits in the TIMx_CR1 register.

PWM edge-aligned mode

Upcounting configuration

Upcounting is active when the DIR bit in the TIMx_CR1 register is low. Refer to Section: Upcounting Mode. In the following example, we consider PWM mode 1. The reference PWM signal OCxREF is high as long as TIMx_CNT <TIMx_CCRx else it becomes low. If the compare value in TIMx_CCRx is greater than the auto-reload value (in TIMx_ARR) then OCxREF is held at ’1’. If the compare value is 0 then OCxREF is held at ’0’. Figure 200 shows some edge-aligned PWM waveforms in an example where TIMx_ARR=8.

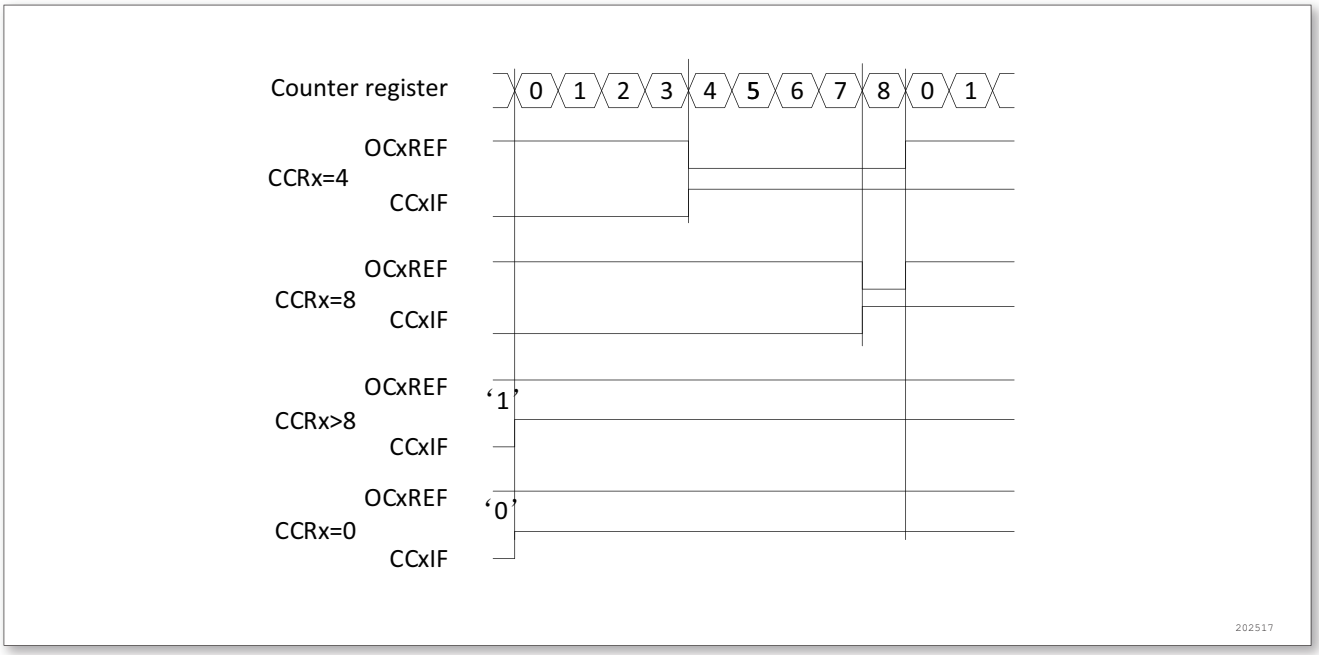

Figure 200. Edge-aligned PWM Waveforms (ARR=8)

15.3.10 Complementary outputs and dead-time insertion

The basic timers (TIM16/17) can output two complementary signals and manage the switching-off and the switching-on instants of the outputs. This time is generally known as dead-time and it has to be adjusted, depending on the devices connected to the outputs and their characteristics (intrinsic delays of level-shifters, delays due to power switches).

User can select the polarity of the outputs (main output OCx or complementary OCxN) independently for each output. This is done by writing to the CCxP and CCxNP bits in the TIMx_CCER register.

The complementary signals OCx and OCxN are activated by a combination of several control bits: the CCxE and CCxNE bits in the TIMx_CCER register and the MOE, OISx, OISxN, OSSI and OSSR bits in the TIMx_BDTR and TIMx_CR2 registers. Refer to Table 52 Output Control Bits for Complementary OCx and OCxN Channels with Break Feature for more details. In particular, the dead-time is activated when switching to the IDLE state (MOE falling down to 0).

Dead-time insertion is enabled by setting both CCxE and CCxNE bits, and the MOE bit if the break circuit is present. Each channel is provided with a 10-bit dead-time generator. From a reference waveform OCxREF, it generates 2 outputs OCx and OCxN. If OCx and OCxN are active high:

- The OCx output signal is the same as the reference signal except for the rising edge, which is delayed relative to the reference rising edge.
- The OCxN output signal is opposite with the reference signal except for the rising edge, which is delayed relative to the reference falling edge.

If the delay is greater than the width of the active output (OCx or OCxN) then the corresponding pulse is not generated.

The following figures show the relationships between the output signals of the dead-time generator and the reference signal OCxREF. (We suppose CCxP=0, CCxNP=0, MOE=1, CCxE=1 and CCxNE=1).

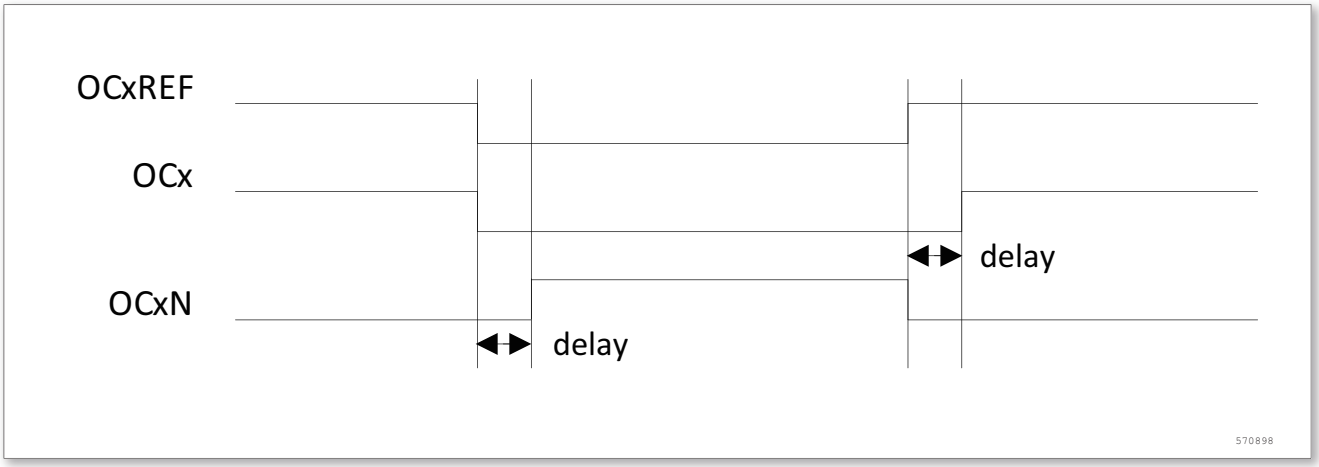

Figure 201. Complementary Output with Dead-time Insertion

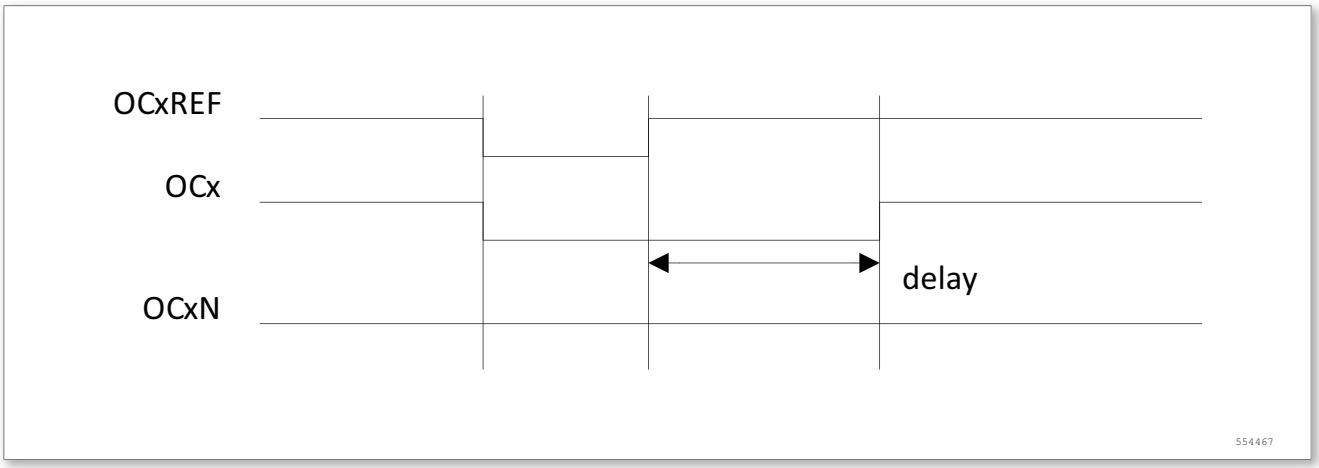

Figure 202. Dead-time Waveforms with Delay Greater Than the Negative Pulse

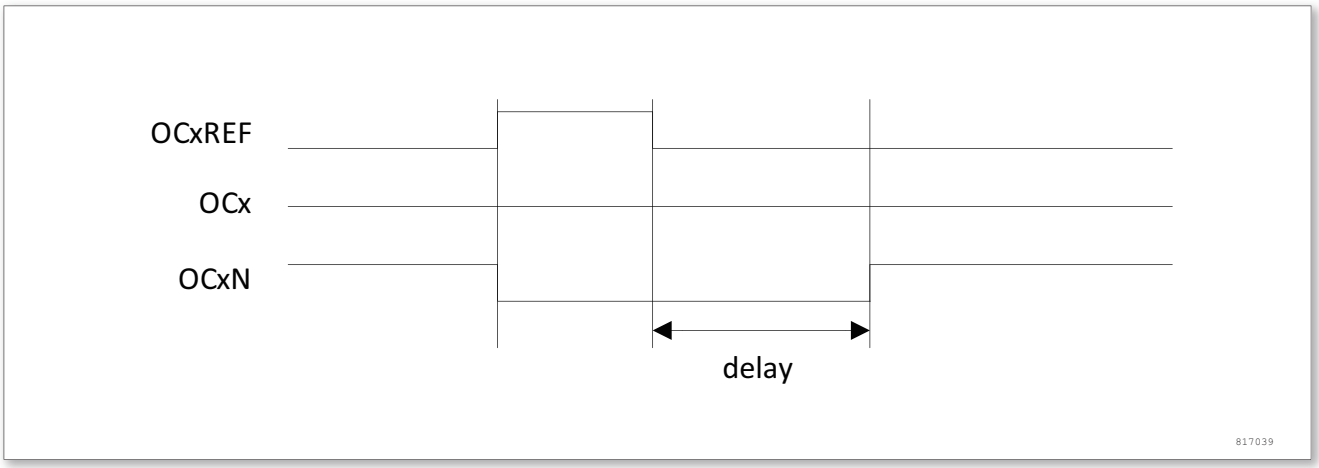

Figure 203. Dead-time Waveforms with Delay Greater Than the Positive Pulse

The dead-time delay is the same for each of the channels and is programmable with the DTG bits in the TIMx_BDTR register. Refer to section 15.4.13: TIM16/17 Break and Dead-time Register (TIMx_BDTR) for delay calculation.

In output mode (forced, output compare or PWM), OCxREF can be re-directed to the OCx

output or to OCxN output by configuring the CCxE and CCxNE bits in the TIMx_CCER register.

This allows the user to send a specific waveform (such as PWM or static active level) on one output while the complementary remains at its inactive level. Other possibilities are to have both outputs at inactive level or both outputs active and complementary with dead-time.

Note: When only OCxN is enabled (CCxE=0, CCxNE=1), it is not complemented and becomes active as soon as OCxREF is high. For example, if CCxNP=0 then OCxN=OCxREF. On the other hand, when both OCx and OCxN are enabled (CCxE=CCxNE=1) OCx becomes active when OCxREF is high whereas OCxN is complemented and becomes active when OCxREF is low.

15.3.11 Using the break function

When using the break function, the output enable signals and inactive levels are modified according to additional control bits (MOE, OSSI and OSSR bits in the TIMx_BDTR register, OISx and OISxN bits in the TIMx_CR2 register). In any case, the OCx and OCxN outputs cannot be set both to active level at a given time. Refer to Table 52 Output Control Bits for Complementary OCx and OCxN Channels with Break Feature for more details. The break source can be either the break input pin or a clock failure event, generated by the Clock Security System (CSS), from the Reset Clock Controller. When exiting from reset, the break circuit is disabled and the MOE bit is low. User can enable the break function by setting the BKE bit in the TIMx_BDTR register. The break input polarity can be selected by configuring the BKP bit in the same register. BKE and BKP can be modified at the same time. The delay of 1 APB clock period occurs before writing BKE and BKP bits. Therefore, the written bits can be read after one APB clock period.

Because MOE falling edge can be asynchronous, a resynchronization circuit has been inserted between the actual signal (acting on the outputs) and the synchronous control bit (accessed in the TIMx_BDTR register). It results in some delays between the asynchronous and the synchronous signals. In particular, if MOE is written to 1 whereas it was low, a delay (dummy instruction) must be inserted before reading it correctly. This is because the user writes an asynchronous signal, but reads a synchronous signal.

When a break occurs (selected level on the break input):

- The MOE bit is cleared asynchronously, putting the outputs in inactive state, idle state or in reset state (selected by the OSSI bit). This feature functions even if the MCU oscillator is off.
- Each output channel is driven with the level programmed in the OISx bit in the TIMx_CR2 register as soon as MOE=0. If OSSI=0 then the timer releases the enable output else the enable output remains high.
- In case of complementary output:
  - The outputs are first put in reset state inactive state (depending on the polarity). This is done asynchronously so that it works even if no clock is provided to the timer.
  - If the timer clock is still present, then the dead-time generator is reactivated in

order to drive the outputs with the level programmed in the OISx and OISxN bits after a dead-time. Even in this case, OCx and OCxN cannot be driven to their active level together. Note that because of the resynchronization on MOE, the dead-time duration is a bit longer than usual (around 2 ck_tim clock cycles).

  - If OSSI=0 then the timer releases the enable outputs else the enable outputs remain or become high as soon as one of the CCxE or CCxNE bits is high.

- The break status flag (BIF bit in the TIMx_SR register) is set. An interrupt can be generated if the BIE bit in the TIMx_DIER register is set. A DMA request can be sent if the BDE bit in the TIMx_DIER register is set.
- If the AOE bit in the TIMx_BDTR register is set, the MOE bit is automatically set again at the next update event UEV. This can be used to perform a regulation, for instance. Else, MOE remains low until it is written to ‘1’ again. In this case, it can be used for security and the break input can be connected to an alarm from power drivers, thermal sensors or any security components.

Note: The break input is acting on level. Thus, the MOE cannot be set while the break input is active (neither automatically nor by software). In the meantime, the status flag BIF cannot be cleared.

The break can be generated by the BRK input which has a programmable polarity and an enable bit BKE in the TIMx_BDTR Register.

In addition to the break input and the output management, a write protection has been implemented inside the break circuit to safeguard the application. It allows freezing the configuration of several parameters (dead-time duration, OCx/OCxN polarities and state when disabled, OCxM configurations, break enable and polarity). The user can choose from three levels of protection selected by the LOCK bits in the TIMx_BDTR register. Refer to section 15.4.13: Break and Dead-time Register (TIM16/17_BDTR). The LOCK bits can be written only once after an MCU reset.

The following figure shows an example of behavior of the outputs in response to a break:

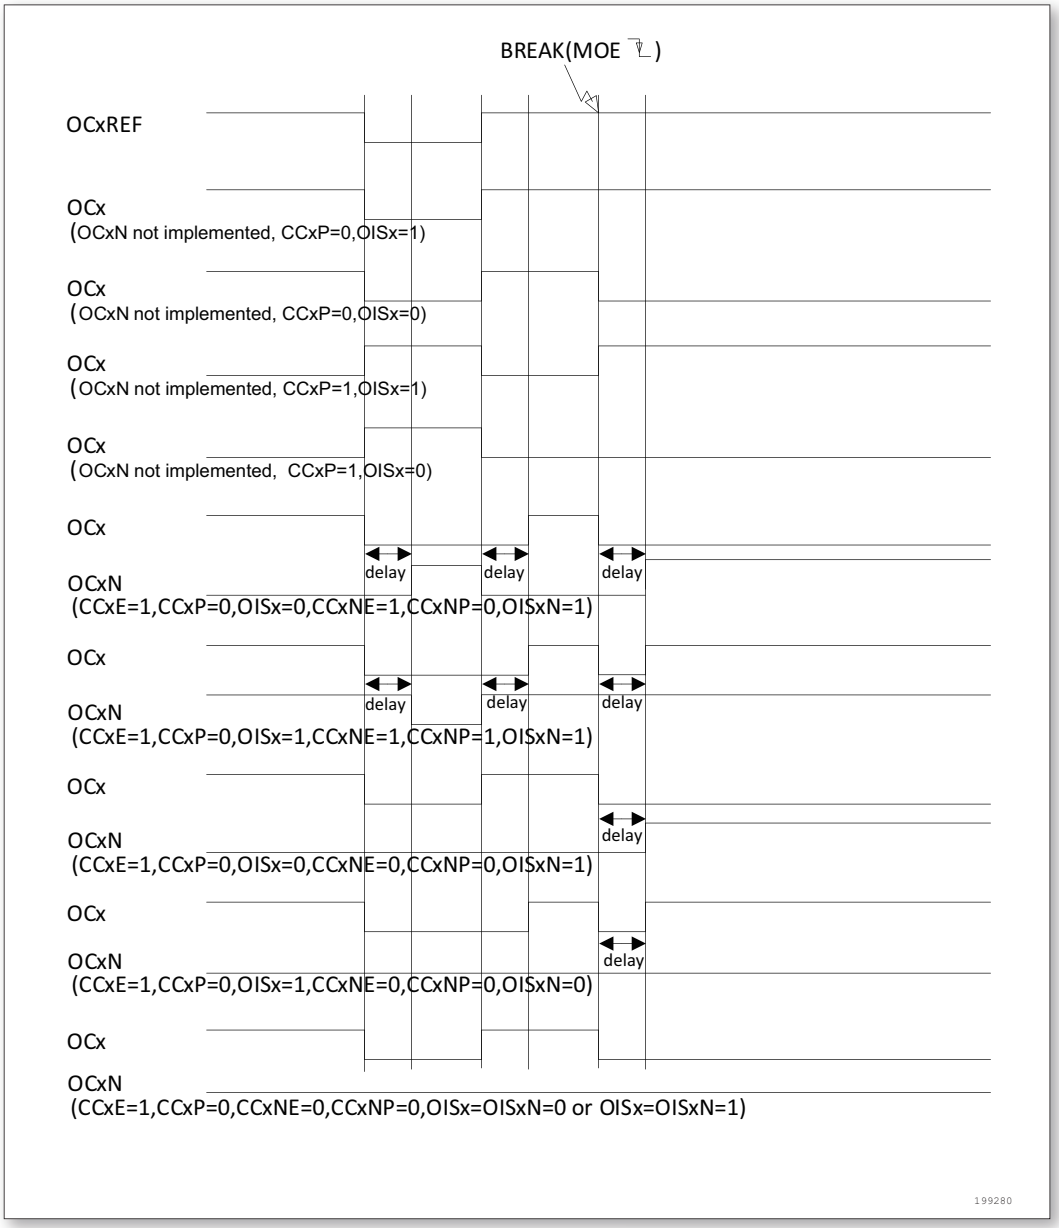

Figure 204. Output Behavior in Response to A Break

15.3.12 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay. Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. Select One-pulse mode by setting the OPM bit in the TIMx_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- In upcounting: CNT < CCRx ≤ ARR (in particular, 0 < CCRx)

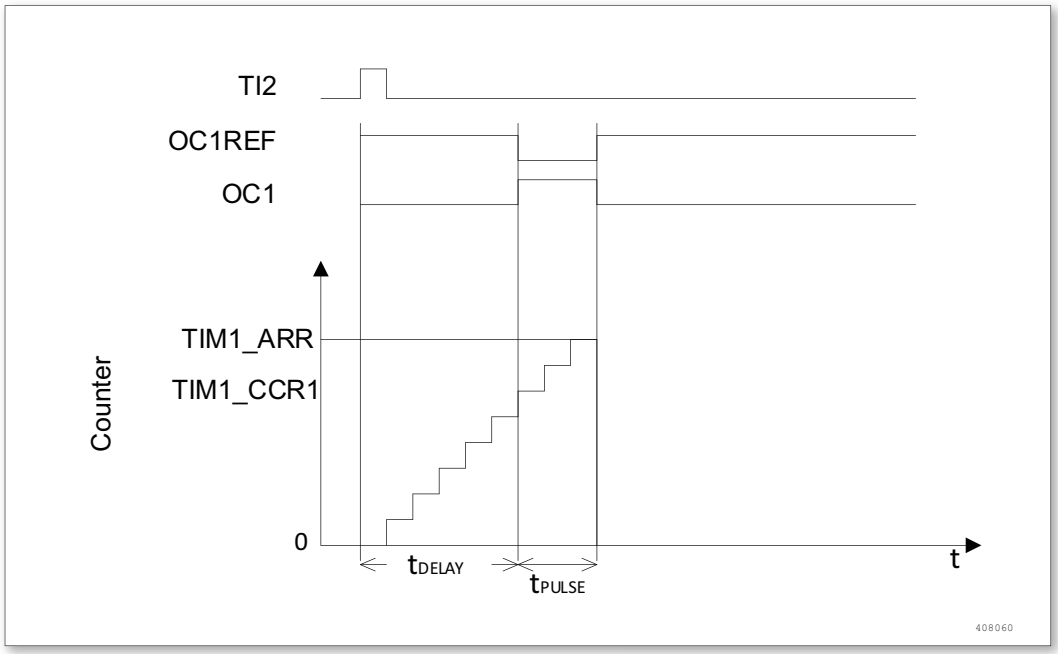

Figure 205. Example of One Pulse Mode

For example the user may want to generate a positive pulse on OC1 with a length of tPULSE and after a delay of t_{DELAY} as soon as a positive edge is detected on the TI2 input pin.

Let’s use TI2FP2 as trigger 1:

- Map TI2FP2 to TI2 by writing CC2S=’01’ in the TIMx_CCMR1 register.
- TI2FP2 must detect a rising edge, write CC2P=’0’ in the TIMx_CCER register.
- Configure TI2FP2 as trigger for the slave mode controller (TRGI) by writing TS=’110’ in the TIMx_SMCR register.
- TI2FP2 is used to start the counter by writing SMS to ‘110’ in the TIMx_SMCR register (trigger mode).
- The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler)
- The tDELAY is defined by the value written in the TIMx_CCR1 register.
- tPULSE is defined by the difference between the auto-load value and the comparison value (TIMx_ARR - TIMx_CCR1).
- Let us say the user wants to build a waveform with a transition from ‘0’ to ‘1’ when a compare match occurs and a transition from ‘1’ to ‘0’ when the counter reaches the auto-reload value. To do this, enable PWM mode 2 by writing OC1M=111 in the TIMx_CCMR1 register. The user can optionally enable the preload registers by writing OC1PE=’1’ in the TIMx_CCMR1 register and ARPE in the TIMx_CR1 register. In this case the compare value must be written in the TIMx_CCR1 register, the auto-reload value in the TIMx_ARR register, generate an update by modifying the UG bit and wait for external trigger event on TI2. CC1P is written to ‘0’ in this example.

In our example, the DIR and CMS bits in the TIMx_CR1 register should be low.The user only wants one pulse (Single mode), so ’1’ must be written in the OPM bit in the TIMx_CR1

register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0). The repetition mode can be selected by setting OPM = ‘0’ in TIMx_CR1 register.

15.3.13 Debug mode

When the microcontroller enters debug mode (Cortex^{TM}-M0 halted), the TIMx counter either continues to work normally or stops, depending on DBG_TIMx_STOP configuration bit in DBG module.

15.4.1 TIM16/17 control register 1(TIM16/17_CR1)

Offset address: 0x00

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						CKD		ARPE	Reserved			OPM	URS	UDIS	CEN
						rw	rw	rw				rw	rw	rw	rw

Bit	Field	Type	Reset	Description
15: 10	Reserved			Reserved, always read as 0.
9: 8	CKD	rw	0x00	Clock division The 2 bits indicates the division ratio between the timer clock (CK_INT) frequency and the sampling frequency used by the digital filters (ETR, TIx). 00: $t_{DTS} = t_{CK\_INT}$ 01: $t_{DTS} = 2 \times t_{CK\_INT}$ 10: $t_{DTS} = 4 \times t_{CK\_INT}$ 11: Reserved
7	ARPE	rw	0x00	Auto-reload preload enable 0: TIMx_ARR register is not buffered 1: TIMx_ARR register is buffered
6: 4	Reserved			Reserved, always read as 0.
3	OPM	rw	0x00	One pulse mode 0: Counter is not stopped at update event 1: Counter stops counting at the next update event (clearing the bit CEN)
2	URS	rw	0x00	Update request source This bit is set and cleared by software to select the UEV. 0: Any of the following events generate an update interrupt or DMA request if enabled.These events can be: - Counter overflow/underflow - Setting the UG bit - Update generation through the slave mode controller 1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.
1	UDIS	rw	0x00	Update disable This bit is set and cleared by software to enable/disable UEV event generation. 0: UEV enabled. The Update (UEV) event is generated by one of the following events: - Counter overflow/underflow - Setting the UG bit - Update generation through the slave mode controller Buffered registers are then loaded with their preload values 1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC, CCRx). However, the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit	Field	Type	Reset	Description
0	CEN	rw	0x00	Counter enable 0: Counter disabled 1: Counter enabled. In the one pulse mode, CEN is automatically cleared when an update event occurs. Note: External clock, gated mode and encoder mode can work only if the CEN bit has been previously set by software. However, trigger mode can set the CEN bit automatically by hardware.

15.4.4 TIM16/17 interrupt enable register(TIM16/17_SR)

Offset address: 0x10

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						CC1OF	Res.	BIF	TIF	COMIF	Reserved			CC1IF	UIF
						rc_w0		rc_w0	rc_w0	rc_w0				rc_w0	rc_w0

Bit	Field	Type	Reset	Description
15: 10	Reserved			Reserved, always read as 0.
9	CC1OF	rc_w0	0x00	Capture/Compare 1 overcapture flag This flag is set by hardware only when the corresponding channel is configured in input capture mode 1. It is cleared by software by writing it to ‘0’. 0: No overcapture has been detected. 1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set.
8	Reserved			Reserved, always read as 0.
7	BIF	rc_w0	0x00	Break interrupt flag This flag is set by hardware as soon as the break input goes active. It can be cleared by software if the break input is not active. 0: No break event occurred. 1: An active level has been detected on the break input
6	TIF	rc_w0	0x00	Trigger interrupt flag This flag is set by hardware on trigger event (active edge detected on TRGI input when the slave mode controller is enabled in all modes but gated mode, both edges in case gated mode is selected). It is cleared by software. 0: No trigger event occurred. 1: Trigger interrupt pending.

Bit	Field	Type	Reset	Description
5	COMIF	rc_w0	0x00	COM interrupt flag This flag is set by hardware on COM event (when Capture/compare Control bits - CCxE, CCxNE, OCxM - have been updated). It is cleared by software. 0: No COM event occurred. 1: COM interrupt pending.
4: 2	Reserved			Reserved, always read as 0.
1	CC1IF	rc_w0	0x00	Capture/Compare 1 interrupt flag If channel CC1 is configured as output: This flag is set by hardware when the counter matches the compare value. It is cleared by software. 0: No match 1: The content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register. If the content of TIMx_CCR1 is greater than that of TIMx_ARR, CC1IF flag becomes high in case of counter overflow. If channel CC1 is configured as input: This bit is set by hardware on an update event. It is cleared by software or by reading TIMx_CCR1. 0: No input capture occurred 1: The counter value has been captured (copied) in TIMx_CCR1 register (An edge has been detected on IC1 which matches the selected polarity)
0	UIF	rc_w0	0x00	Update interrupt flag This bit is set by hardware on an update event. It is cleared by software. 0: No update occurred. 1: Update interrupt pending. This bit is set by hardware when the registers are updated: - The update event is generated at overflow regarding the repetition counter value (update if repetition counter= 0) and if the UDIS=0 in the TIMx_CR1 register. - The update event is generated if URS=0 and UDIS=0 in the TIMx_CR1 register and CNT is reinitialized by setting UG bit in TIMx_EGR register through software. - The update event is generated when CNT is reinitialized by a trigger event, and if URS=0 and UDIS=0 in the TIMx_CR1 register.

15.4.5 TIM16/17 event generation register 1(TIM16/17_EGR)

Offset address: 0x14

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								BG	TG	COMG	Reserved			CC1G	UG
								w	w	w				w	w

Bit	Field	Type	Reset	Description
15: 8	Reserved			Reserved, always read as 0.
7	BG	w	0x00	Break generation This bit is set by software in order to generate an event, it is automatically cleared by hardware. 0: No action 1: A break event is generated. MOET bit is cleared and TIF in TIMx_SR register is set. Related interrupt or DMA transfer can occur if enabled.
6	TG	w	0x00	Trigger generation This bit is set by software in order to generate an event, it is automatically cleared by hardware. 0: No action 1: The TIF flag is set in TIMx_SR register. Related interrupt or DMA transfer can occur if enabled.
5	COMG	w	0x00	Capture/Compare control update generation This bit can be set by software, it is automatically cleared by hardware. 0: No action 1: When CCPC bit is set, it allows to update CCxE, CCxNE and OCxM bits Note: This bit acts only on channels that have a complementary output.
4:2	Reserved			Reserved, always read as 0.
1	CC1G	w	0x00	Capture/compare 1 generation This bit is set by software in order to generate a capture/compare event, it is automatically cleared by hardware. 0: No action 1: A capture/compare event is generated on channel 1 If channel CC1 is configured as output: CC1IF flag is set, corresponding interrupt or DMA request is sent if enabled. If channel CC1 is configured as input: The current value of the counter is captured in TIMx_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit	Field	Type	Reset	Description
0	UG	w	0x00	Update generation This bit can be set by software, it is automatically cleared by hardware. 0: No action 1: Reinitialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected).

15.4.6 TIM16/17 capture/compare mode register 1(TIM16/17_CCMR1)

Offset address: 0x18

Reset value: 0x0000

The channels can be used in input (capture mode) or in output (compare mode). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode. For a given bit, OCxx describes its function when the channel is configured in output, ICxx describes its function when the channel is configured in input. So the user must take care that the same bit can have a different meaning for the input stage and for the output stage.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								Res.	OC1M			OC1 PE	OC1 FE	CC1S	
								IC1F				IC1PSC			
								rw	rw	rw	rw	rw	rw	rw	rw

Output compare mode:

Bit	Field	Type	Reset	Description
15: 7	Reserved			Reserved, always read as 0.

Bit	Field	Type	Reset	Description
6: 4	OC1M	rw	0x00	Output compare 1 mode These bits define the behavior of the output reference signal OC1REF from which OC1 are derived. OC1REF is active high whereas OC1 and OC1N active levels depend on CC1P and CC1PN bits respectively. 000: Frozen - The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on OC1REF (only applicable to generating time base). 001: Set channel 1 to active level on match. OC1REF signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1). 010: Set channel 1 to inactive level on match. OC1REF signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1). 011: Toggle - OC1REF toggles when TIMx_CNT=TIMx_CCR1. 100: Force inactive level - OC1REF is forced low. 101: Force active level - OC1REF is forced high. 110: PWM mode 1 - In upcounting, channel 1 is active as long as TIMx_CNT ＜ TIMx_CCR1 else inactive. In downcounting, channel 1 is inactive (OC1REF= ‘0’) as long as TIMx_CNT>TIMx_CCR1 else active (OC1REF=’1’). 111: PWM mode 2 - In upcounting, channel 1 is inactive as long as TIMx_CNT<TIMx_CCR1 else active. In downcounting, channel 1 is active as long as TIMx_CNT>TIMx_CCR1 else inactive. Note 1: This bit is not writable as soon as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S=’00’ (the channel is configured in output). Note 2: In PWM mode 1 or 2, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from “frozen” mode to “PWM” mode.

Bit	Field	Type	Reset	Description
3	OC1PE	rw	0x00	Output compare 1 preload enable 0: Preload register on TIMx_CCR1 disabled. TIMx_CCR1 can be written at anytime, the new value is taken in account immediately. 1: Preload register on TIMx_CCR1 enabled. Read/Write operations access the preload register. TIMx_CCR1 preload value is transferred to the active register at each update event. Note 1: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S=00 (the channel is configured in output). Note 2: The PWM mode can be used without validating the preload register only in one pulse mode (OPM bit set in TIMx_CR1 register). Else the behavior is not guaranteed.
2	OC1FE	rw	0x00	Output compare 1 fast enable This bit is used to accelerate the effect of an event on the trigger in input on the CC output. 0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles. 1: An active edge on the trigger input acts like a compare match on CC1 output. Then, OC is set to the compare level independently from the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OCFE acts only if the channel is configured in PWM1 or PWM2 mode.
1: 0	CC1S	rw	0x00	Capture/Compare 1 selection This bit-field defines the direction of the channel (input/output) as well as the used input. 00: CC1 channel is configured as output 01: CC1 channel is configured as input, IC1 is mapped on TI1 10: CC1 channel is configured as input, IC1 is mapped on TI2 11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register) Note: CC1S bits are writable only when the channel is OFF (CC1E = ’0’ in TIMx_CCER).

Input capture mode:

Bit	Field	Type	Reset	Description
15: 8	Reserved			Reserved, always read as 0.
7: 4	IC1F	rw	0x00	Input capture 1 ?lter This bit-field defines the frequency used to sample TI1 input and the length of the digital filter applied to TI1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output: 0000: No filter, sampling is done at f_{DTS} 0001: Sampling frequency $f_{SAMPLING} = f_{CK\_INT}$, N = 2 0010: Sampling frequency $f_{SAMPLING} = f_{CK\_INT}$, N = 4 0011: Sampling frequency $f_{SAMPLING} = f_{CK\_INT}$, N = 8 0100: Sampling frequency $f_{SAMPLING} = f_{DTS}$, N = 6 0101: Sampling frequency $f_{SAMPLING} = f_{DTS}$, N = 8 0110: Sampling frequency $f_{SAMPLING} = f_{DTS}$, N = 6 0111: Sampling frequency $f_{SAMPLING} = _{DTS}/4$, N = 8 1000: Sampling frequency $f_{SAMPLING} = f_{DTS}/8$, N = 6 1001: Sampling frequency $f_{SAMPLING} = f_{DTS}/8$, N = 8 1010: Sampling frequency $f_{SAMPLING} = f_{DTS}/16$, N = 5 1011: Sampling frequency $f_{SAMPLING} = f_{DTS}/16$, N = 6 1100: Sampling frequency $f_{SAMPLING} = ff_{DTS}/16$, N = 8 1101: Sampling frequency $f_{SAMPLING} = f_{DTS}/32$, N = 5 1110: Sampling frequency $f_{SAMPLING} = f_{DTS}/32$, N = 6 1111: Sampling frequency $f_{SAMPLING} = f_{DTS}/32$, N = 8
3: 2	IC1PSC	rw	0x00	Input capture 1 prescaler This bit-field defines the ratio of the prescaler acting on CC1 input (IC1). The prescaler is reset as soon as CC1E=’0’(TIMx_CCER register). 00: no prescaler, capture is done each time an edge is detected on the capture input. 01: capture is done once every 2 events 10: capture is done once every 4 events 11: capture is done once every 8 events

Bit	Field	Type	Reset	Description
1: 0	CC1S	rw	0x00	Capture/compare 1 This bit-field defines the direction of the channel (input/output) as well as the used input. 00: CC1 channel is configured as output 01: CC1 channel is configured as input, IC1 is mapped on TI1 10: CC1 channel is configured as input, IC1 is mapped on TI2 11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register) Note: CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIMx_CCER).

												rw	rw	rw	rw

Bit	Field	Type	Reset	Description
15: 4	Reserved			Reserved, always read as 0.
3	CC1NP	rw	0x00	Capture/Compare 1 complementary output Polarity 0: OC1N active high 1: OC1N active low
2	CC1NE	rw	0x00	Capture/Compare 1 complementary output enable 0: Off - OC1N inactive 1: On - Signal of OC1N output to relevant pin depends on MOE, OSSI, OSSR, OIS1, OIS1 and CC1E bits.

Bit	Field	Type	Reset	Description
1	CC1P	rw	0x00	Capture/compare 1 output polarity If channel CC1 is configured as output: 0: OC1 active high 1: OC1 active low CC1 channel is configured as input: CC1P/CC1NP bit (IC1 or inverted IC1) is used to select the polarity of TI1FP1 and TI2FP1 as trigger or capture. 00: non-inverted/rising edge: capture is done on a rising edge of TIxFP1 (capture mode), and TIxFP1 is non-inverted; 01: inverted/falling edge: capture is done on a falling edge of TIxFP1 (capture mode), and TIxFP1 is inverted; 10: Reserved, this configuration is not used 11: non-inverted/rising edge: capture is done on the rising and falling edges of non-inverted TIxFP1 (capture mode).
0	CC1E	rw	0x00	Capture/Compare 1 output enable CC1 channel is configured as output: 0: Off - OC1 is not active 1: On - OC1N signal output to relevant pin depends on MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits. CC1 channel is configured as input: This bit determines if a capture of the counter value can actually be done into the input capture/compare register 1 (TIMx_CCR1) or not. 0: Capture disabled. 1: Capture enabled.

Table 52. Output Control Bits for Complementary OCx and OCxN Channels with Break Feature

Control bits					Output states(1)	
MOE bit	OSSI bit	OSSR bit	CCxE bit	CCxNE bit	OCx OCx output state	OCxN output state
1	X	0	0	0	Output Disabled (not driven by the timer) OCx = 0, OCx_EN = 0	Output Disabled (not driven by the timer) OCxN = 0, OCxN_EN = 0
		0	0	1	Output Disabled (not driven by the timer) OCx = 0, OCx_EN = 0	OCxREF + Polarity, OCxN = OCxREF xor CCxNP, OCxN_EN = 1
		0	1	0	OCxREF + Polarity, OCx = OCxREF xor CCxP, OCx_EN = 1	Output Disabled (not driven by the timer) OCxN = 0, OCxN_EN = 0

Control bits					Output states(1)	
MOE bit	OSSI bit	OSSR bit	CCxE bit	CCxNE bit	OCx OCx output state	OCxN output state
		0	1	1	OCxREF + Polarity + dead-time, OCx_EN=1	OCxREF (inverted) + Polarity + dead-time, OCxN_EN = 1
		1	0	0	Output Disabled (not driven by the timer) OCx = CCxP, OCx_EN = 0	Output Disabled (not driven by the timer), OCxN = CCxNP, OCxN_EN = 0
		1	0	1	Off-State (output enabled with inactive state) OCx = CCxP, OCx_EN = 1	OCxREF + Polarity, OCxN = OCxREF xor CCxNP, OCxN_EN = 1
		1	1	0	OCxREF + Polarity, OCx = OCxREF xor CCxP, OCx_EN = 1	Off-State (output enabled with inactive state) OCxN = CCxNP, OCxN_EN = 1
		1	1	1	OCREF + Polarity + dead-time, OCx_EN = 1	OCxREF (inverted) + Polarity + dead-time, OCxN_EN = 1
0	0	X	0	0	Output Disabled (not driven by the timer)	
	0		0	1	Asynchronously: OCx = CCxP , OCx_EN = 0 , OCxN = CCxNP,	
	0		1	0	OCxN_EN = 0；	
	0		1	1	Then if the clock is present: after a dead-time OCx = OISx , OCxN = OISxN, Assuming that OISx and OISxN do not correspond to OCx and OCxN both in active	
	1		0	0	Off-State (output enabled with inactive state)	
	1		0	1	Asynchronously: OCx = CCxP, OCx_EN = 1, OCxN = CCxNP,	
	1		1	0	OCxN_EN = 1；	
	1		1	1	Then if the clock is present: after a dead-time OCx = OISx , OCxN = OISxN, Assuming that OISx and OISxN do not correspond to OCx and OCxN both in active	

1. When both outputs of a channel are not used (CCxE = CCxNE = 0), the OISx, OISxN, CCxP and CCxNP bits must be kept cleared.

Note: The state of the external IO pins connected to the omplementary OCx and OCxN channels depends on the OCx and OCxN channel states and the GPIO and AFIO registers.

Bit	Field	Type	Reset	Description
15: 0	PSC	rw	0x0000	Prescaler value The counter clock frequency (CK_CNT) is equal to f_{CK_PSC} /(PSC + 1). PSC contains the value to be loaded in the active prescaler register at each update event (including when the counter is cleared through UG bit of TIMx_EGR register or through trigger controller when configured in ”reset mode”)

15.4.10 TIM16/17 auto-reload register(TIM16/17_ARR)

Offset address: 0x2C

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ARR															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit	Field	Type	Reset	Description
15: 0	ARR	rw	0x0000	Prescaler value ARR is the value to be loaded in the actual auto-reload register. Refer to section 15.3.1 for more details about ARR update and behavior. The counter is blocked while the auto-reload value is null.

15.4.11 TIM16/17 repetition counter register(TIM16/17_RCR)

Offset address: 0x30

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								REP							
								rw	rw	rw	rw	rw	rw	rw	rw

Bit	Field	Type	Reset	Description
15: 8	Reserved			Reserved, always read as 0.
7: 0	REP	rw	0x00	Repetition counter value These bits allow the user to set up the update rate of the compare registers (i.e. periodic transfers from preload to active registers) when preload registers are enable, as well as the update interrupt generation rate, if this interrupt is enable. Each time the REP_CNT related upcounter reaches zero, an update event is generated and it restarts counting from REP value. As REP_CNT is reloaded with REP value only at the repetition update event U_RC, any write to the TIMx_RCR register is not taken in account until the next repetition update event. It means in PWM mode (REP + 1) corresponds to the number of PWM periods.

15.4.12 TIM16/17 Capture/compare register 1(TIM16/17_CCR1)

Offset address: 0x34

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CCR1															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit	Field	Type	Reset	Description
15: 0	CCR1	rw	0x0000	Capture/Compare 1 value If CC1 channel is configured as output: CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs. The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on OC1 output. If CC1 channel is configured as input: CCR1 contains the counter value transferred by the last input capture 1 event (IC1).

15.4.13 TIM16/17 break and dead-time register(TIM16/17_BDTR)

Offset address: 0x44

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MOE	AOE	BKP	BKE	OSSR	OSSI	LOCK		DTG							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Note: As the bits AOE, BKP, BKE, OSSI, OSSR and DTG[7:0] can be write-locked depending on the LOCK configuration, it can be necessary to configure all of them during the first write access to the TIMx_BDTR register.

Bit	Field	Type	Reset	Description
15	MOE	rw	0x00	Main output enable This bit is cleared asynchronously by hardware as soon as the break input is active. It is set by software or automatically depending on the AOE bit. It is acting only on the channels which are configured in output. 0: OC and OCN outputs are disabled or forced to idle state. 1: OC and OCN outputs are enabled if their respective enable bits are set (CCxE, CCxNE in TIMx_CCER register). See section 15.4.7: TIM16/17 Capture/compare Enable Register (TIM16/17_CCER) for more details.
14	AOE	rw	0x00	Automatic output enable 0: MOE can be set only by software 1: MOE can be set by software or automatically at the next update event (if the break input is not be active) Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).
13	BKP	rw	0x00	Break polarity 0: Break input BRK is active low 1: Break input BRK is active high Note 1: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register). Note 2: This bit can only be written after the delay of one APB clock.
12	BKE	rw	0x00	Break enable 0: Break inputs (BRK and CSS clock failure event) disabled 1: Break inputs (BRK and CSS clock failure event) enabled Note 1: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register). Note 2: This bit can only be written after the delay of one APB clock.

Bit	Field	Type	Reset	Description
11	OSSR	rw	0x00	Off-state selection for Run mode This bit is used when MOE=1 on channels configured as complementary outputs. OSSR is not implemented if no complementary output is implemented in the timer. See OC/OCN enable description for more details (section 15.4.7: capture/compare enable register (TIMx_CCER)). 0: When inactive, OC/OCN outputs are disabled (OC/OCN enable output signal=0). 1: When inactive, OC/OCN outputs are enabled and inactive level is output as soon as CCxE=1 or CCxNE=1, and then set OC/OCN enable output signal to 1. Note: This bit can not be modified as long as LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).
10	OSSI	rw	0x00	Off-state selection fo Idle mode This bit is used when MOE=0 on channels configured as outputs. See OC/OCN enable description for more details (section 15.4.7: capture/compare enable register (TIMx_CCER)). 0: When inactive, OC/OCN outputs are disabled (OC/OCN enable output signal=0). 1: When inactive, OC/OCN outputs are enabled and inactive level is output as soon as CCxE=1 or CCxNE=1, and then set OC/OCN enable output signal to 1 Note: This bit can not be modified as long as LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).

Bit	Field	Type	Reset	Description
9: 8	LOCK	rw	0x00	Lock configuration These bits offer a write protection against software errors. 00: LOCK OFF - No bit is write-protected. 01: LOCK Level 1 = DTG, BKE, BKP, AOE bits in TIMx_BDTR register, and OISx/OISxN bits in TIMx_CR2 register can no longer be written. 10: LOCK Level 2 = LOCK Level 1 + CC Polarity bits (CCxP/CCxNP bits in TIMx_CCER register, as long as the related channel is configured in output through the CCxS bits) as well as OSSR and OSSI bits can no longer be written. 11: LOCK Level 3 = LOCK Level 2 + CC Control bits (OCxM and OCxPE bits in TIMx_CCMRx registers, as long as the related channel is configured in output through the CCxS bits) can no longer be written. Note: The LOCK bits can be written only once after the reset. Once the TIMx_BDTR register has been written, their content is frozen until the next reset.
7: 0	DTG	rw	0x00	Dead-time generator setup This bit-field defines the duration of the dead-time inserted between the complementary outputs. It is assumed that DT corresponds to this duration. DTG[7: 5] = 0xx: DT = (DTG[7: 0] + 1) × t_{dtg}, t_{dtg} = t_{DTS}; DTG[7: 5] = 10x: DT = (DTG[5: 0] + 1 + 64) × t_{dtg}, t_{dtg} = 2 × t_{DTS}; DTG[7: 5] = 110: DT = (DTG[4: 0] + 1 + 32) × t_{dtg}, t_{dtg} = 8 × t_{DTS}; DTG[7: 5] = 111: DT = (DTG[4: 0] + 1 + 32) × t_{dtg}, t_{dtg} = 16 × t_{DTS}; Example if t_{DTS} = 125ns(8MHz), dead-time possible values are: 125ns to 15875ns by 125 nS steps; 16μs to 31750ns by 250 nS steps; 32μs to 63μs by 1 μs steps; 64μs to 126μs by 2 μs steps; Note: This bit-field can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

15.4.14 TIM16/17 DMA DMA control register(TIM16/17_DCR)

Offset address: 0x48

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved			DBL					Reserved			DBA				
			rw	rw	rw	rw	rw				rw	rw	rw	rw	rw

Bit	Field	Type	Reset	Description
15: 13	Reserved			Reserved, always read as 0.
12: 8	DBL	w	0x00	DMA burst length This bit field defines the burst transfer in the continuous mode (the timer detects a burst transfer when a read or a write access to the TIMx_DMAR register address is performed), namely, the number of transfers: 00000: 1 byte 00001: 2 bytes 00010: 3 bytes .... 10001: 18 bytes
7: 5	Reserved			Reserved, always read as 0.
4: 0	DBA	w	0x00	DMA base address These bits define the base-address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address. Example: 00000: TIMx_CR1 00001: TIMx_CR2 00010: TIMx_SMCR ..... Example: To complete the following transfer: DBL = 7 , DBA = TIMx_CR1, at this time, the transfer starts from the address of TIMx_CR1 to/from 7 consecutive registers.

15.4.15 TIM16/17 address for full transfer(TIM16/17_DMAR)

Offset address: 0x4C

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DMAB															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit	Field	Type	Reset	Description
15: 0	DMAB	w	0x0000	DMA register for burst accesses A read or write operation to the TIMx_DMAR register accesses the register located at the following address: (Address of TIMx_CR1) + (DBA + DMA index) x 4, where, TIMx_CR1 address is the address of the control register 1 (TIMx_CR1); DBA is the DMA base address configured in TIMx_DCR register; DMA index is the offset automatically controlled by the DMA transfer, depending on DBL configured in TIMx_DCR.

Example of how to use DMA concurrent operation:

In this example, the concurrency function of the timer DMA is used, to transfer the contents of the CCRx register to the CCRx register in half words. The procedures are as follows:

1. Configure the relevant DMA channels:
   (a) The device address of DMA channel is DMAR register address
   (b) The memory address of DMA channel covers the RAM buffer address of data transferred to CCRx register by DMA.
   (c) Data transferred = 3 (see the following Note)
   (d) Notification mode disabled
2. Configure the DBA and DBL bits of the DCR register: DBL = 3 transfers, DBA = 0xE.
3. Enable TIMx Update DMA Request (set UDE bit in DIER register)
4. Enable TIMx
5. Enable DMA channel

Note: In this example, all CCRx registers are updated all at one time. If the CCRx register needs to be updated twice, the data transferred shall be 6, and the RAM buffer zone shall contain data1, data2, data3, data4, data5 and data6. The data is transferred to the CCRx register as follows: in case of the first DMA update request, data1 is transferred to CCR2, data2 transferred to CCR3, and data3 transferred to CCR4; data4 is transferred to CCR2 in case of the second DMA update interrupt request, data5 transferred to CCR3 and data6 transferred to CCR4.

16 Independent watchdog(IWDG)

Independent watchdog(IWDG)

16.1 (IWDG introduction)

The devices have two embedded watchdog peripherals which offer a combination of high safety level, timing accuracy and flexibility of use. Both watchdog peripherals (Independent and Window) serve to detect and resolve malfunctions due to software failure, and to trigger system reset or an interrupt (window watchdog only) when the counter reaches a given timeout value.

The independent watchdog (IWDG) is clocked by its own dedicated low-speed clock (LSI) and thus stays active even if the main clock fails. The window watchdog (WWDG) clock is prescaled from the APB1 clock and has a configurable time-window that can be programmed to detect abnormally late or early application behavior.

The IWDG is best suited to applications which require the watchdog to run as a totally independent process outside the main application, but have lower timing accuracy constraints. The WWDG is best suited to applications which require the watchdog to react within an accurate timing window.

16.2 IWDG main features

- Free-running downcounter
- Clocked from an independent RC oscillator (can operate in Standby and Stop modes)
- Reset (if watchdog activated) when the downcounter value of 0x000 is reached

16.3 Functional description

The following figure shows the functional blocks of the independent watchdog module.

When the independent watchdog is started by writing the value 0xCCCC in the Key register (IWDG_KR), the counter starts counting down from the reset value of 0xFFF. When it reaches the end of count value (0x000) a reset signal is generated (IWDG reset).

Whenever the key value 0xAAAA is written in the IWDG_KR register, the IWDG_RLR value is reloaded in the counter and the watchdog reset is prevented.

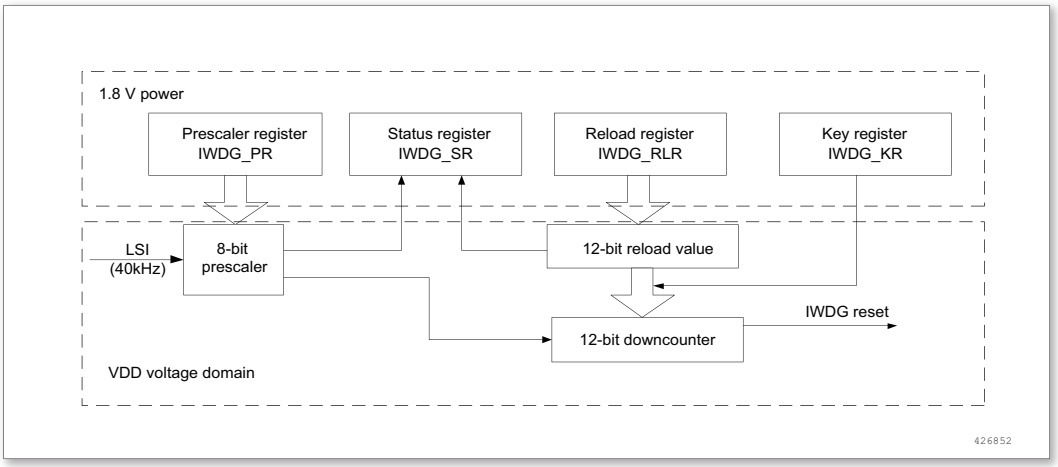

Figure 206. Independent Watchdog Block Diagram

Note: The watchdog function is implemented in the V_{DD} voltage domain, still functional in Stop and Standby modes.

Table 53. Min/max IWDG Timeout Period (in ms) at 40 kHz (LSI)

Prescaler divider	PR [2:0] bits	Min timeout RL[11:0] = 0x000	Max timeout
/4	0	0.1	409.6
/8	1	0.2	819.2
/32	3	0.8	3276.8
/64	4	1.6	6553.6
/128	5	3.2	13107.2
/256	(6 or 7)	6.4	26214.4

Note: These timings are given for a 40 kHz clock but the microcontroller internal RC frequency can vary between 30 kHz –60 kHz.
In addition, even if the frequency of the oscillator is accurate, the exact timing still depends on the phase difference between the APB interface clock and the oscillator clock.
As a result, there will always be a complete oscillator period that is uncertain.

16.3.1 Hardware watchdog

If the user activates the 'Hardware Watchdog' function in the select bit (refer to the section "Embedded Flash"), the watchdog will automatically run after the system power-on reset; if the software does not write the corresponding value to the key register before the counter ends counting, the system reset will occur.

16.3.2 Register access protection

The IWDG_PR and IWDG_RLR registers are write-protected. To modify the values of these two registers, you must first write 0x5555 to the IWDG_KR register. Writing to this register with a different value will disrupt the sequence and the registers will be reprotected. The reload operation (i.e. writing 0xAAAA) will also activate the write protection.

The status register indicates whether the prescaler value and the downcounter are being updated.

16.3.3 Debug mode

When the microcontroller enters debug mode (CPU core halted), the IWDG counter either continues to work normally or stops, depending on DBG_IWDG_STOP configuration bit in DBG module. For more details, refer to sections of debug modules.

16.4 IWDG register description

Table 54. Overview of IWDG Registers

Offset	Acronym	Register Name	Reset	Section
0x00	IWDG_KR	Key register	0x00000000	section 16.4.1
0x04	IWDG_PR	Prescaler register	0x00000000	section 16.4.2

				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit	Field	Type	Reset	Description
31 : 12	Reserved			Always read as 0.

Bit	Field	Type	Reset	Description
11 : 0	RL	rw	0xFFF	Watchdog counter reload value These bits are write access protected. They are written by software to define the value to be loaded in the watchdog counter each time the value 0xAAAA is written in the IWDG_KR register. The watchdog counter counts down from this value. The timeout period is a function of this value and the clock prescaler. Note: Reading this register returns the reload value from the VDD voltage domain. This value may not be up to date/valid if a write operation to this register is ongoing on this register. For this reason, the value read from this register is valid only when the RVU bit in the IWDG_SR register is reset.

16.4.4 Status register(IWDG_SR)

Offset address: 0x0C

Reset value: 0x0000 0000 (not reset by Standby mode)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved														RVU	PVU
														r	r

Bit	Field	Type	Reset	Description
31 : 2	Reserved			Always read as 0.
1	RVU	r	0x00	Watchdog counter reload value update This bit is set by hardware to indicate that an update of the reload value is ongoing. It is reset by hardware when the reload value update operation is completed in the V_{DD} voltage domain (takes up to 5 RC 40 kHz cycles). Reload value can be updated only when RVU bit is reset.
0	PVU	r	0x00	Watchdog prescaler value update This bit is set by hardware to indicate that an update of the prescaler value is ongoing. It is reset by hardware when the prescaler update operation is completed in the V_{DD} voltage domain (takes up to 5 RC 40 kHz cycles). Prescaler value can be updated only when PVU bit is reset.

Note: If several reload values or prescaler values are used by application, it is mandatory to wait

until RVU bit is reset before changing the reload value and to wait until PVU bit is reset before changing the prescaler value. However, after updating the prescaler and/or the reload value it is not necessary to wait until RVU or PVU is reset before continuing code execution (even in case of low-power mode entry, the write operation is taken into account and will complete).

17 Window watchdog(WWDG)

Window watchdog(WWDG)

17.1 WWDG introduction

The window watchdog is used to detect the occurrence of a software fault, usually generated by external interference or by unforeseen logical conditions, which causes the application program to abandon its normal sequence. The watchdog circuit generates an MCU reset on expiry of a programmed time period, unless the program refreshes the contents of the downcounter before the T6 bit becomes cleared. An MCU reset is also generated if the 7-bit downcounter value (in the control register) is refreshed before the downcounter has reached the window register value. This implies that the counter must be refreshed in a limited window.

17.2 WWDG main features

- Programmable free-running downcounter
- Conditional reset:
  - Reset (if watchdog activated) when the downcounter value becomes less than 0x40
  - Reset (if watchdog activated) if the downcounter is reloaded outside the window
- Early wakeup interrupt (EWI): triggered (if enabled and the watchdog activated) when the downcounter is equal to 0x40. It is used to reload the counter, thus preventing WWDG reset.

17.3 Functional description

If the watchdog is activated (the WDGA bit is set in the WWDG_CR register) and when the 7-bit downcounter (T[6:0] bits) rolls over from 0x40 to 0x3F (T6 becomes cleared), it initiates a reset. If the software reloads the counter while the counter is greater than the value stored in the window register, then a reset is generated.

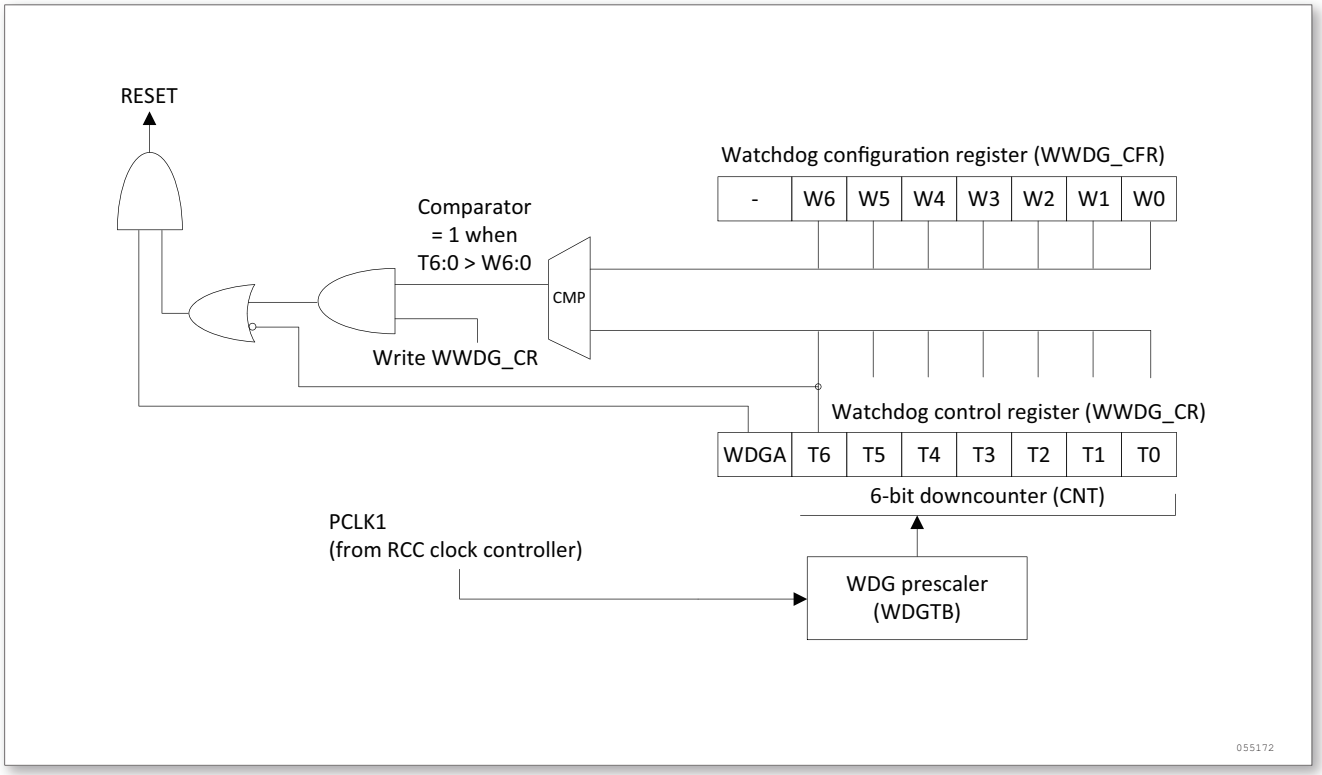

Figure 207. Watchdog Block Diagram

The application program must write in the WWDG_CR register at regular intervals during normal operation to prevent an MCU reset. This operation must occur only when the counter value is lower than the window register value. The value to be stored in the WWDG_CR register must be between 0xFF and 0xC0.

• Enabling the watchdog

The watchdog is always disabled after a reset. It is enabled by setting the WDGA bit in the WWDG_CR register, then it cannot be disabled again except by a reset.

• Controlling the downcounter

This downcounter is free-running, counting down even if the watchdog is disabled. When the watchdog is enabled, the T6 bit must be set to prevent generating an immediate reset.

The T[5:0] bits contain the number of increments which represents the time delay before the watchdog produces a reset. The timing varies between a minimum and a maximum value due to the unknown status of the prescaler when writing to the WWDG_CR register.

The Configuration register (WWDG_CFR) contains the high limit of the window: To prevent a reset, the downcounter must be reloaded when its value is lower than the window register value and greater than 0x3F. The above figure describes the window watchdog process.

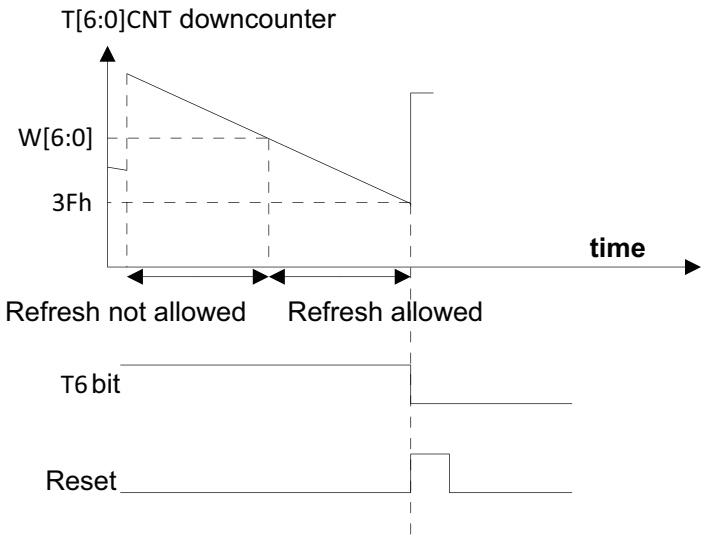
Another way to reload the counter is to use the early wakeup interrupt (EWI). This interrupt is enabled by setting the WEI bit in the WWDG_CFR register. It is generated when the downcounter reaches 0x40, and the corresponding interrupt service routine (ISR) can be used to load counters, so as to prevent WWDG reset. The interrupt can be cleared by writing a ’0’ to the WWDG_SR register.

Note: The T6 bit can be used to generate a software reset (the WDGA bit is set and the T6 bit is cleared).

17.4 How to program the watchdog timeout

The figure below shows the linear relationship (in mS) between the 6-bit count value loaded into the Watchdog Counter (CNT) and the watchdog delay time. This figure can be used as a reference for rapid calculation without taking into account time deviations. If higher precision is required, you can use the calculation formula provided in the figure below.

Warning: When writing to the WWDG_CR register, always write 1 in the T6 bit to avoid generating an immediate reset.



The formula to calculate the WWDG timeout value is given by:

$$T_{WWDG} = T_{PCLK1} \times 4096 \times 2^{WDGTB} \times (T[5:0]+1) \quad \text{(mS)}$$

Where:

T_{WWDG}: WWDG timeout

T_{PCLK1}: APB1 clock period measured in ms

Minimum and maximum timeout values at PCLK1=36 MHz

WDGTB	Min. timeout value	Max. timeout value
0	**113µS**	**7.28mS**
1	**227µS**	**14.56mS**
2	**455µS**	**29.12mS**
3	**910µS**	**58.25mS**

Figure 208. Window Watchdog Timing Diagram

17.5 Debug mode

When the microcontroller enters debug mode (CPU core halted), the WWDG counter either continues to work normally or stops, depending on DBG_WWDG_STOP configuration bit in DBG module. For more details, refer to sections of debug modules.

17.6 WWDG register description

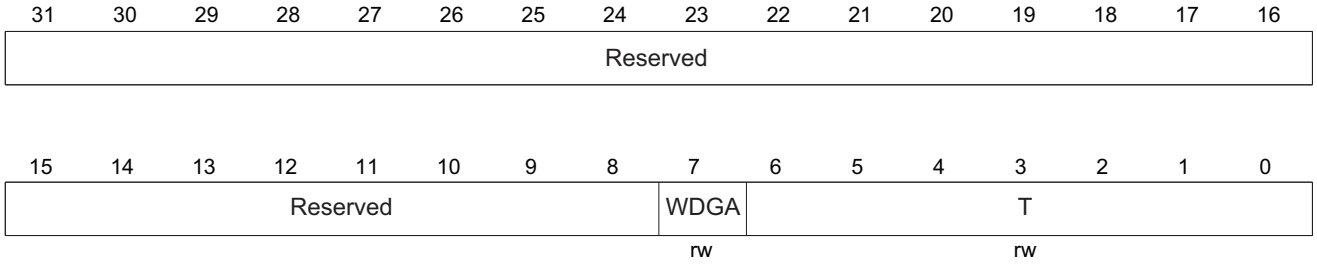
Table 55. Overview of WWDG Registers

Offset	Acronym	Register Name	Reset	Section
0x00	WWDG_CR	Control register	0x0000007F	section 17.6.1
0x04	WWDG_CFGR	Configuration register	0x0000007F	section 17.6.2
0x08	WWDG_SR	Status register	0x00000000	section 17.6.3

17.6.1 Control register(WWDG_CR)

Offset address: 0x00

Reset value: 0x0000 007F

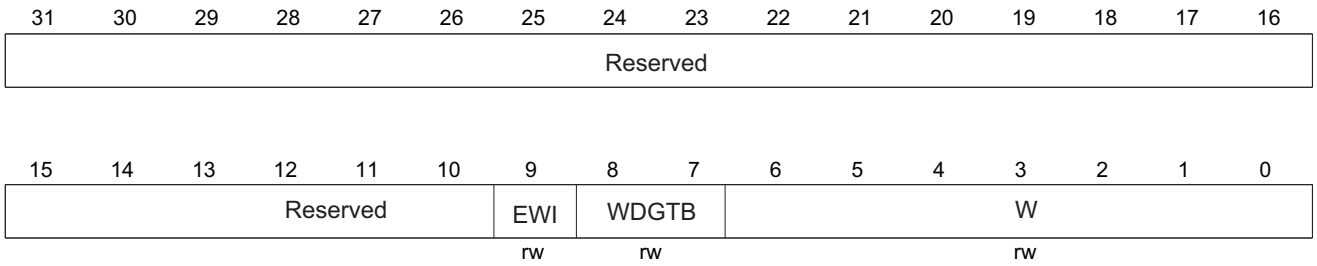


Bit	Field	Type	Reset	Description
31:8	Reserved			Reserved, always read as 0.
7	WDGA	rw	0x00	Activation bit This bit is set by software and only cleared by hardware after a reset. When WDGA = 1, the watchdog can generate a reset. 0: Watchdog disabled 1: Watchdog enabled
6:0	T	rw	0x7F	7 - bit counter These bits contain the value of the watchdog counter. It is decremented every(4096x2^{WDGTB})PCLK1 cycles.A reset is produced when it rolls over from 0x40 to 0x3F (T6 becomes cleared).

17.6.2 Configuration register(WWDG_CFGR)

Offset address: 0x04

Reset value: 0x0000 007F

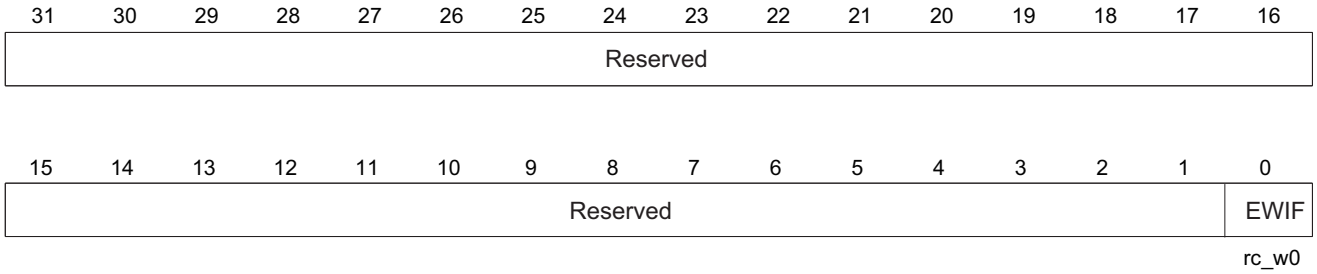


Bit	Field	Type	Reset	Description
31:10	Reserved			Reserved, always read as 0.
9	EWI	rw	0x00	Early wakeup interrupt When set, an interrupt occurs whenever the counter reaches the value 0x40. This interrupt is only cleared by hardware after a reset.
8:7	WDGTB	rw	0x00	Timer base The time base of the prescaler can be modified as follows: 00: CK Counter Clock (PCLK1 div 4096) div1 01: CK Counter Clock (PCLK1 div 4096) div2 10: CK Counter Clock (PCLK1 div 4096) div4 11: CK Counter Clock (PCLK1 div 4096) div8
6:0	WINDOW	rw	0x7F	7-bit window value These bits contain the window value to be compared to the downcounter.

17.6.3 Status register(WWDG_SR)

Offset address: 0x08

Reset value: 0x0000 0000



Bit	Field	Type	Reset	Description
31:1	Reserved			Reserved, always read as 0.
0	EWIF	rc_w0	0x00	Early wakeup interrupt flag This bit is set by hardware when the counter has reached the value 0x40. It must be cleared by software by writing '0'. A write of '1' has no effect. This bit is also set if the interrupt is not enabled.

18 Serial peripheral interface(SPI)

Serial peripheral interface(SPI)

18.1 SPI description

The SPI interface is widely used for board-level communication between different devices, such as the extended serial Flash, ADC, etc. Devices from many IC manufacturers support the SPI interface.

The serial peripheral interface (SPI) allows full-duplex, synchronous, serial communication with external devices. Applications can communicate by querying status or SPI interrupts.

18.2 Main features

- Fully compatible with Motorola SPI specification
- Support DMA requests
- Full-duplex synchronous transfers on three lines
- 16-bit programmable baud rate generator
- Master or slave operation
- 8-byte FIFO receiving/transmitting
- In master mode, SPI clock reaches pclk/2 (pclk: APB clock); in slave mode, SPI clock is up to pclk/4
- Programmable clock polarity and phase
- Programmable data sequence, MSB first or LSB first
- Support one-host and multiple-slave operations
- Support simultaneous transmission and reception of 1 ~ 32-bit data
- In addition to 8-bit data transmission and reception, the remaining 1 ~ 32-bit data transmission and reception only supports LSB mode, not supporting MSB mode.
- Support 8 transmit buffers and receive buffers for corresponding configuration data bits (Data size)
- Interrupt drive operation
  - The transmitting end is null and the end overflows
  - Received data is valid, and data overflows at the receiving end
  - Complete reception in SPI master mode, and the transmitting end is null

18.3 Functional description

18.3.1 General

The block diagram of SPI is shown below

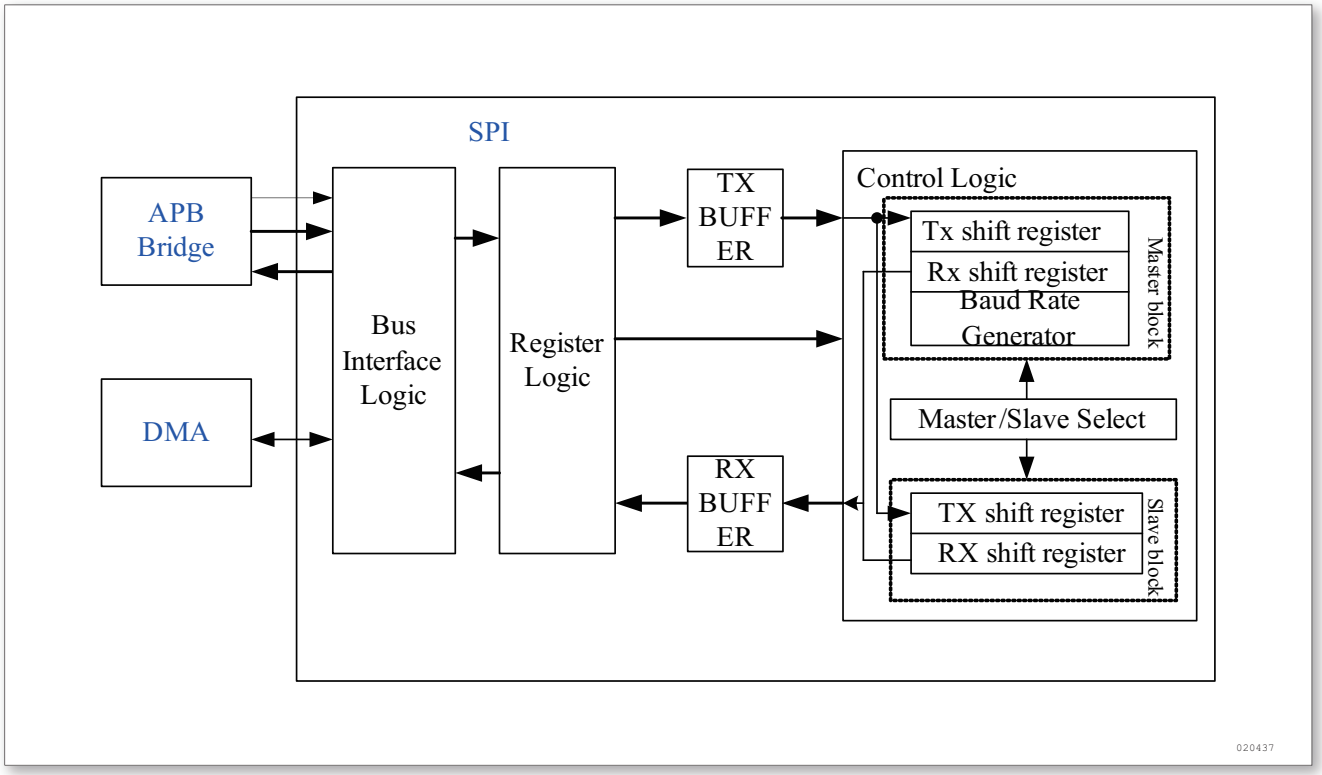


Figure 209. SPI Block Diagram

The SPI enables receiving and transmitting 1 ~ 32-bit data simultaneously. The SPI can be configured as the slave mode or the master mode in a host environment. Four possible timing relationships can be selected by configuring the clock polarity CPOL and phase CPHA. It supports programmable data sequence, i.e. MSB first or LSB first.

The same clock is used for the transmission and reception. Data is clocked on the rising or falling edge of the clock, latching the data on the opposite valid edge of SCLK. Since the SPI is used to exchange data, the data must be read after transferring even if the data is invalid. In SPI mode, the clock and polarity of the master shall be the same as that of the slave to be communicated.

Usually, the SPI is connected to external devices through four pins:

MOSI: Master Out / Slave In data. This pin can be used to transmit data in master mode and receive data in slave mode.

SCK: Serial Clock output for SPI masters and input for SPI slaves.

NSS: Slave select. This is an optional pin to select a master/slave device. This pin acts as a 'chip select' to let the SPI master communicate with slaves individually and to avoid contention on the data lines. Slave NSS inputs can be driven by standard IO ports on the master device. The NSS pin may also be used as an output if enabled and driven low if the SPI is in master mode. At this time, all NSS pins from devices connected to the Master NSS pin see a low level.

- MISO: Master In / Slave Out data. This pin can be used to transmit data in slave mode and receive data in master mode.
- MOSI: Master Out / Slave In data. This pin can be used to transmit data in master mode

and receive data in slave mode.

- SCK: Serial Clock output for SPI masters and input for SPI slaves.
- NSS: Slave select. This is an optional pin to select a master/slave device. This pin acts as a 'chip select' to let the SPI master communicate with slaves individually and to avoid contention on the data lines. Slave NSS inputs can be driven by standard IO ports on the master device. The NSS pin may also be used as an output if enabled and driven low if the SPI is in master mode. At this time, all NSS pins from devices connected to the Master NSS pin see a low level.

An example of interconnections between a single master and a single slave is illustrated below.

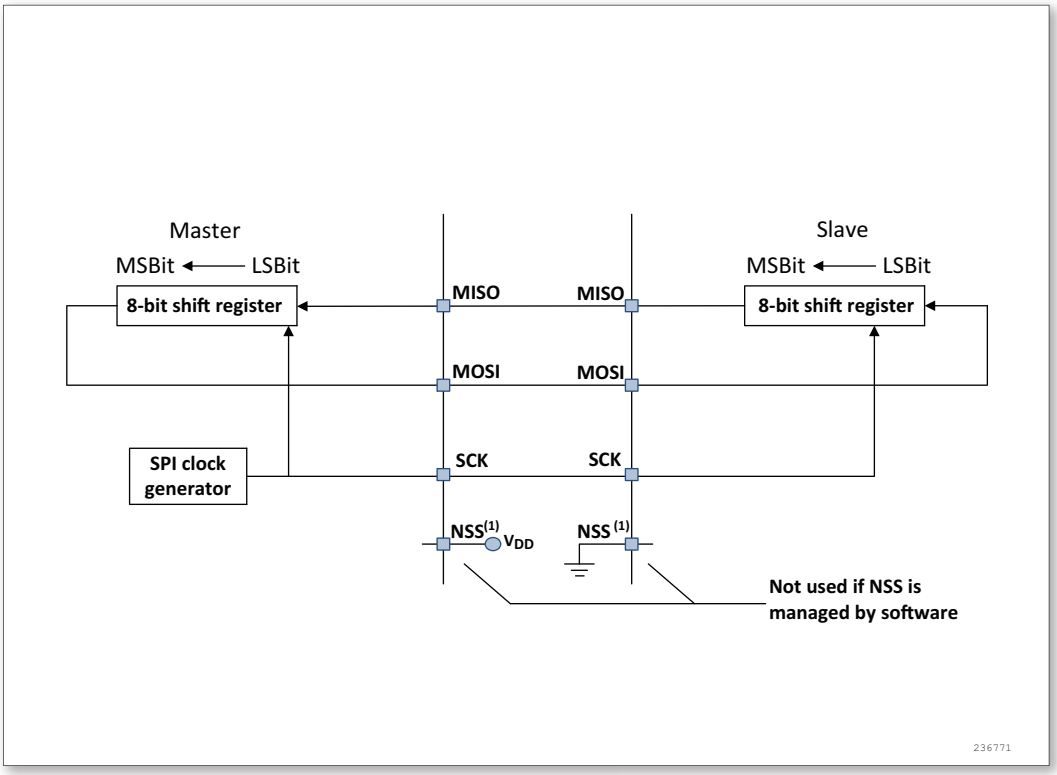

Figure 210. Single Master/Single Slave Application

The MOSI pins are connected together and the MISO pins are connected together. In this way, data is transferred serially between master and slave (most significant bit (MSB) first).

The communication is always initiated by the master. When the master device transmits data to a slave device via the MOSI pin, the slave device responds via the MISO pin. This implies full-duplex communication with both data out and data in synchronized with the same clock signal (which is provided by the master device via the SCK pin).

Clock phase and clock polarity

Four possible timing relationships may be chosen by software, using the CPOL and CPHA bits in the SPI_CCTL register. The CPOL (clock polarity) bit controls the steady state value of the clock when no data is being transferred. This bit affects both master and slave modes. If CPOL is reset, the SCK pin has a low-level idle state, namely, the low level

between two transfers. If CPOL is set, the SCK pin has a high-level idle state, namely, the high level between two transfers.

If the CPHA (clock phase) bit is set, the first data bit is latched on the second edge on the SCK (falling edge if the CPOL bit is set; rising edge if the CPOL bit is reset), and the data bit received is sampled. The SPI changes the serial data during the first SCK clock transition (when the clock changes in the opposite direction of the idle state) and captures the data on the next edge.

If the CPHA (clock phase) bit is cleared, the first data bit is latched on the first edge on the SCK (falling edge if the CPOL bit is reset; rising edge if the CPOL bit is set), and the data bit received is sampled. The SPI captures the the serial data during the first SCK clock transition (the clock changes in the opposite direction of the idle state) and the data is changed on the next edge.

The combination of the CPOL (clock polarity) and CPHA (clock phase) bits selects the data capture clock edge. Figure 211 shows an SPI transfer with the four combinations of the CPHA and CPOL bits. The diagram may be interpreted as a master or slave timing diagram where the SCK pin,the MISO pin, the MOSI pin are directly connected between the master and the slave device.

High-speed transmission

Considering the sensitivity to board-level delay in high-speed transmission mode, adjust the time for adjust the time of the transmitting phase and the received samples by setting TXEDGE and RXEDGE control bits in the SPI_CCTL register.

- In the slave mode, if TXEDGE is 1, the data is immediately sent to the data bus for high-speed mode (SPBRG = 4); when the bit is 0, the data is sent to the data bus after a valid clock edge for low-speed mode (SPBRG > 4).
- In master mode, if RXEDGE is 1, the data is sampled in the middle of the transmitted data bit; when the bit is 0, the data is sampled on the tail clock edge of the transmitted data bit (for high-speed mode)

1. The SPIEN bit must be cleared to disable the SPI before changing the CPOL/CPHA bit.
2. The master and slave must be configured as the same timing mode.
3. The idle state of SCK must be the same as the polarity specified by the SPI_CCTL register. When CPOL is 1, the SCK shall be set high in the idle state. When CPOL is 0, SCK shall be set low in the idle state.

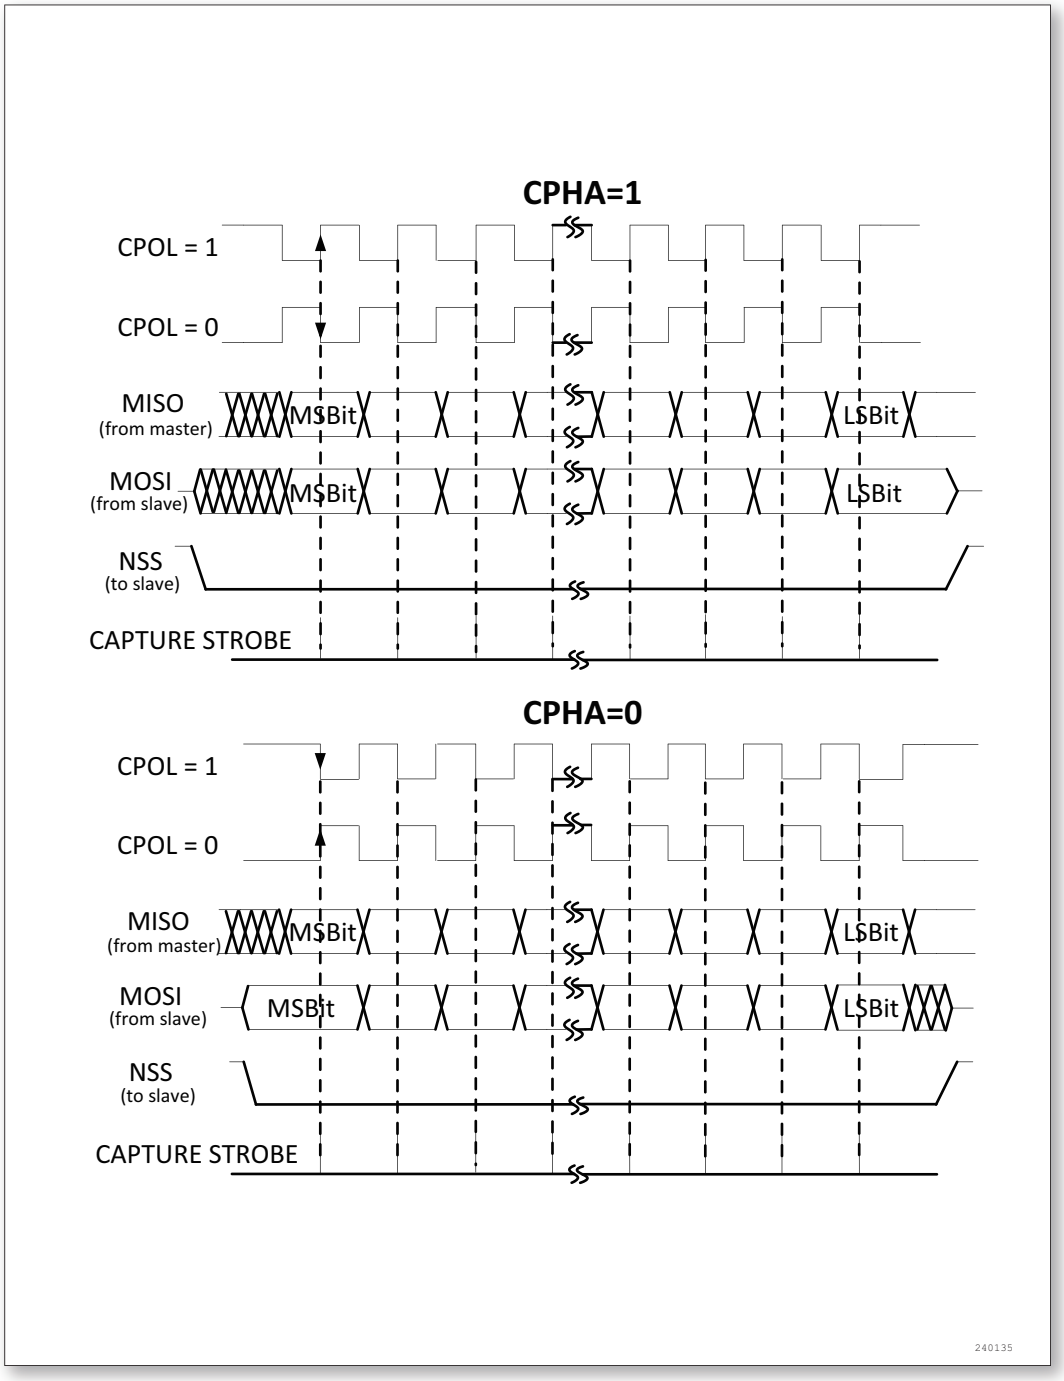

Figure 211. Data Clock Timing Diagram

Data frame format

Data can be shifted out either MSB-first or LSB-first depending on the value of the LSBFE bit in the SPI_CCTL Register. Each data frame is 7 or 8 bits long depending on the SPILEN bit in the SPI_CCTL register. The selected data frame format is applicable to transmission and/or reception.

In addition, the register SPI_EXTCTL can be configured, with the data frame length of 1 ~ 32 bits. Configuration is required to during the application: the DW8_32 bit of the SPI_CCTL register is set to ’0’, and the LSBFE bit of the SPI_CCTL register is set to ’1’

and the SPILEN bit is set to '1'. In conjunction with DMA data transmission, the data length of the DMA needs to be configured as 8 bits.

18.3.2 SPI slave mode

In the slave configuration, the serial clock is received on the SCK pin from the master device. The setting in the SPI_SPBRG register does not affect the data transfer rate.

Procedure

1. Set the SPILEN bit to define 7- or 8-bit data frame format.
2. Select the CPOL and CPHA bits to define one of the four relationships between the data transfer and the serial clock. For correct data transfer, the CPOL and CPHA bits must be configured in the same way in the slave device and the master device.
3. The frame format (MSB-first or LSB-first depending on the value of the LSBFE bit in the SPI_CCTL register) must be the same as the master device.
4. Clear the MDOE bit and set the SPIEN bit, making corresponding pins work in SPI mode. In this configuration, the MOSI pin is used as the data input, and MISO as data output.

Transmit sequence

The data byte is parallel-loaded into the transmitting buffer during the write operation.

The transmit sequence begins when the slave device receives the clock signal and the first data bit appears on its MOSI pin, then the first bit is sent. The remaining bits are loaded into the shift-register. The TX_INTF flag in the SPI_INTSTAT register is set on the transfer of data from the transmitting buffer to the shift register, and an interrupt is generated if the TXIEN bit in the SPI_INTEN register is set.

Receive sequence

For the receiver, when data transfer is complete:

- The Data in shift register is transferred to receiving buffer and the RX_INTF flag (SPI_INTSTAT register) is set.
- An Interrupt is generated if the RXIEN bit is set in the SPI_INTEN register.

After the last sampling clock edge, the RXNE bit is set, a copy of the data byte received in the shift register is moved to the receiving buffer. When the SPI_RXREG register is read, the SPI peripheral returns this buffered value.

18.3.3 SPI master mode

In the master configuration, the serial clock is generated on the SCK pin.

Procedure

1. Define the serial clock baud rate through SPI_SPBRG register.
2. Select the CPOL and CPHA bits to define the phase relation between the data transfer and the serial clock.
3. Set the SPILEN bit to define 8- or 7-bit data frame format.
4. Configure the LSBFE bit in the SPI_CCTL register to define the frame format.

5. If data is only received and not sent, the SPI_RNDNR register shall be set, and the bytes to be received shall be defined.
6. The MDOE and SPIEN bits must be set.

In this configuration, the MOSI pin is a data output, the MISO pin is a data input, and NSS is the select signal output of slave device.

Transmit sequence

The transmit sequence begins when a byte is written in the transmitting buffer. The data byte is parallel-loaded into the shift register (from the internal bus) during the first bit transmission, and then shifted out serially to the MOSI pin; MSB first or LSB first depends on the LSBFE bit in the SPI_CCTL register. The TX_INTF flag is set on the transfer of data from the transmitting buffer to the shift register, and an interrupt is generated if the TXIEN bit in the SPI_INTEN register is set.

Receive sequence

For the receiver, when data transfer is complete:

- The Data in shift register is transferred to receiving buffer and the RX_INTF flag (SPI_INTSTAT register) is set.
- An Interrupt is generated if the RXIEN bit is set in the SPI_INTEN register.

After the last sampling clock edge, the RXNE bit is set, a copy of the data byte received in the shift register is moved to the receiving buffer. When the SPI_RXREG register is read, the SPI peripheral returns this buffered value.

If only data is received and not transmitted, the RXMATCH_INTF bit is set to ’1’ after receiving the bytes defined by RXDNR, indicating that all data has been received, and the clock signal is no longer transmitted in Master mode.

18.3.4 Status flags

For convenient software operation, the application can monitor the state of the SPI bus with four current status flags and seven interrupt status flags. The current status flag is read-only and is automatically set and cleared by hardware; the interrupt status flag is set when an event occurs and generates a CPU interrupt when the interrupt is enabled, and it can be cleared by software.

The SPI is configured with 8-byte transmit buffer and receive buffer. The CPU enables reading and writing 1 or 4 bytes at a time according to the DW8_32-bit setting of SPI_GCTL. Based on the configuration of DW8_32, the transmit and receive buffers respectively have one-byte flag or a status flag of valid data.

Table 56. SPI Status

Classification	Status flag	Buffer and signal status
Interrupt status	TX_INTF	According to the DW8_32 setting, there is at least one space for valid data, enabling writing the transmitting data register for one time.

Interrupt status	RX_INTF	According to the DW8_32 setting, there is at least one space for valid data, enabling reading the transmitting data register for one time.
Interrupt status	UNDERRUN_INTF	Transmitting buffer is null and repeated transmission occurs
Interrupt status	RXOERR_INTF	Receiving buffer is non-null and overwritten
Interrupt status	RXMATCH_INTF	Non-null, the last data is transferred to the receiving buffer
Interrupt status	RXFULL_INTF	Receiving buffer is full and unable to receive new data
Interrupt status	TXEPT_INTF	Transmitting buffer is null and unable to send data
Current status	RXAVL_4BYTE	Receiving buffer is loaded with valid data more than 4 bytes
Current status	TXFULL	Transmitting buffer is full
Current status	TXEPT	Transmitting buffer is null
Current status	RXAVL	The receiving buffer is non-null and enables receiving at least one byte

When the TXTLF of the SPI_GCTL register is 00, TX_INTF is set when the transmitting buffer is configured with one or more free data spaces. When TXTLF is 01, TX_INTF is set when the transmitting buffer is configured with more than half of the free space.

When the RXTLF of the SPI_GCTL register is 00, RX_INTF is set when the receiving buffer is loaded with one or more valid data. When RXTLF is 01, RX_INTF is set when the receiving buffer is loaded with more than half of the valid data.

18.3.5 Baud rate setting

The baud rate is the frequency of the generated SCLK, which is typically the division of PCLK. The BRG is a 16-bit baud rate generator, and the SPBREG register is used to control the count period of the 16-bit counter.

The desired baud rate and f_{pclk} (frequency of the APB module) are given, and the value calculated from the formula shown in the table below is set to the SPBRG register. The X in the table below is equal to the value of the SPBRG register (2 ~ 65535).

Table 57. Baud Rate Formula

Mode	Formula
SPI mode	Baud rate = f_{pclk}/X

18.3.6 SPI communication using DMA

To operate at its maximum speed, the SPI needs to be fed with the data for transmission and the data received on the receive buffer should be read to avoid overrun. To facilitate the transfers, the SPI features a DMA capability implementing a simple request/acknowledge protocol.

A DMA access is requested when DMAEN bit in the SPI_GCTL register is enabled. DMA requests of transmitting buffer and receive buffer are enabled by DMAEN.

- In transmission, a DMA request is issued if TXTLF in SPI_GCTL register is set to 00 and the transmitting buffer is configured with one or more free data spaces; when TXTLF is set to 01 and the transmitting buffer is configured with more than half free space, a DMA request is generated, enabling only one DMA transfer. In the process, the data size and that of transmitting buffer depend on DW8_32.
- In reception, a DMA transfer request is issued if RXTLF in SPI_GCTL register is set to 00 and the receive buffer is loaded with one or more valid data; when RXTLF is set to 01 and the receive buffer is loaded with more than half valid data, a DMA request is generated, enabling only one DMA transfer. In the process, the data size and that of receive buffer depend on DW8_32.

19 I2C interface (I2C)

I2C interface (I2C)

19.1 I2C introduction

I2C (inter-integrated circuit) bus Interface serves as an interface between the microcontroller and the serial I2C bus. It provides multimaster capability, and controls all I2C bus-specific sequencing, protocol, arbitration and timing.

The I2C bus is a two-wire serial interface, in which two-wire bit serial data (SDA) and serial clock (SCL) lines are used to transmit information between the devices connected to bus. Each device is configured with a unique address identification and can be used as a transmitter or receiver. Moreover, the device can also be considered as a master or slave during data transmission. The master is the device that initializes the data transfer of the bus and generates a clock signal enabling the transmission. At that time, any addressed device is considered as a slave.

I2C can operate in standard mode (data transmission rate: 0 ～100 Kbps) and fast mode (maximum data transmission rate: 400 Kbps).

19.2 I2C main features

- Parallel-bus2C protocol converter
- Half-duplex synchronous operation
- Act as Master or Slave
- Support 7-bit and 10-bit addresses
- Support standard mode (100 Kbps) and fast mode (400 Kbps)
- Generate Start, Stop, Resend Start, Acknowledge Signals for detection
- Only support one master device in master mode
- 2 bytes of transmitting and receive buffers respectively
- Provide burr-free circuit to SCLI and SDAI
- Support DMA operation
- Support interrupt and query operations

19.3 I2C protocol

19.3.1 Start and Stop conditions

When the bus is in the idle state, SCL and SDA are simultaneously tied high with the external pull-up resistor. Before the master enables the data transfer, a Start condition must be generated. When the SCL line is high, the SDA line switches from high to low, to indicate the Start condition. A Stop condition is generated when the master disables

the transfer. The SCL line is high and the SDA line switches from low to high, indicating a Stop condition.

The figure below shows the timing diagram for the Start and Stop conditions. During data transfer, SDA must remain stable when SCL is 1.

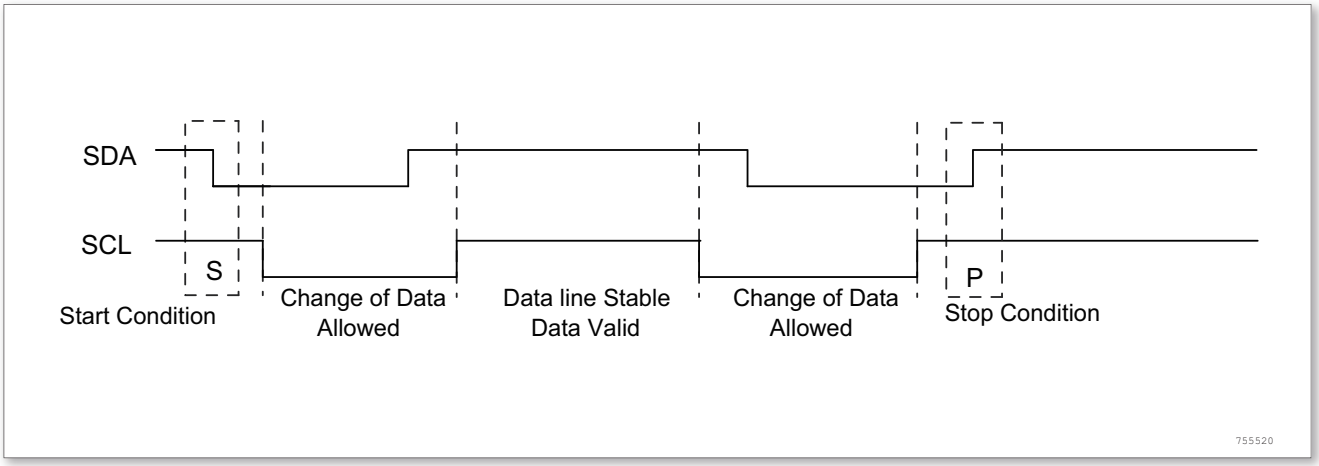

Figure 212. Start and Stop Conditions

19.3.2 Slave address protocol

I2C has two address formats: 7-bit address format and 10-bit address format.

7-bit address format

The following figure shows the first 7 bits (bit 7:1; slave address) of a byte transmitted after the Start condition (S), and the lowest bit (bit 0) is the data direction bit. When bit 0 is 0, it indicates that the master writes data to the slave; 1 represents that the master reads data from the slave.

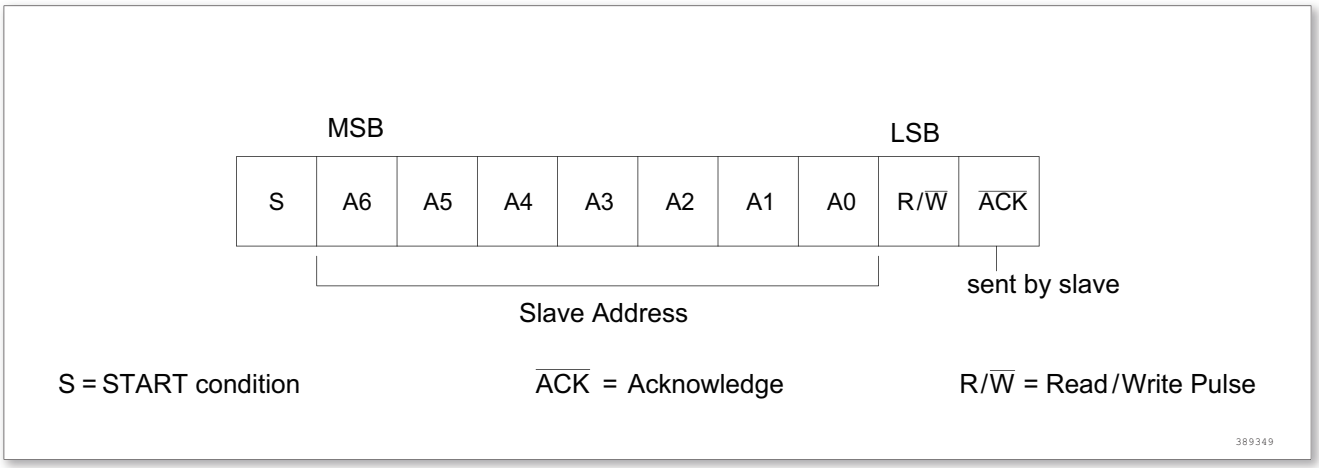

Figure 213. 7-bit Address Format

10-bit address format

In the 10-bit address format, 2 bytes are transmitted to transfer the 10-bit address. The description of the first byte of the transmission bit is as follows: The first 5 bits (bit 7:3) are used to signal the next 10-bit transmission of the slave. The last two bits (bit 2:1) of the first byte are bit 9:8 of the slave address, and the lowest bit (bit 0) is the data direction bit

(R/W). The second byte of the data transferred is the lower eight bits of the 10-bit address.

The details are as follows:

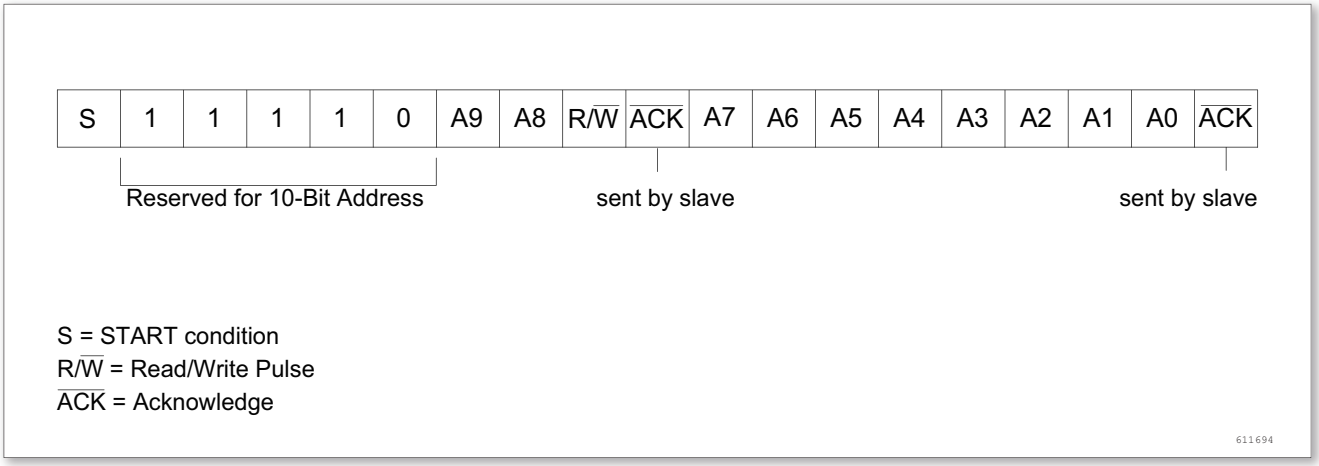

Figure 214. 10-bit Address Format

The following table defines the special purpose and reserved addresses of the first byte of I2C:

Table 59. First Byte of I2C

Slave address	R/W bit	Description
0000 000	0	General call address: the data is sent to the receive buffer via I2C, so as to generate a general call interrupt
0000 000	1	Start byte
0000 001	X	CBUS address: I2C interface ignores this access
0000 010	X	Reserved
0000 011	X	Reserved
0000 1xx	X	Reserved
1111 1xx	X	Reserved
1111 0xx	X	10-bit slave addressing

19.3.3 Transmission and reception protocols

The master, master transmitter or receiver, initializes data transfer and sends or receives data from the bus. The slave, as a slave transmitter or slave receiver, responds to the master's request, sending or receiving data.

Master transmitter and slave receiver

All data is transmitted in byte format, with the unlimited bytes per transfer. When the master sends the address and R/W bit or the master sends a byte of data to the slave, the slave shall generate a response signal (ACK). When the slave receiver fails to generate an ACK response, the master will generate a Stop condition, to abort the transmission. When the slave fails to respond, SDA shall be set high, making the master generate a Stop condition.

When the master transmitter transmits the data, the slave receiver responds to the master transmitter by generating an ACK after each byte received, as shown in the following figure.

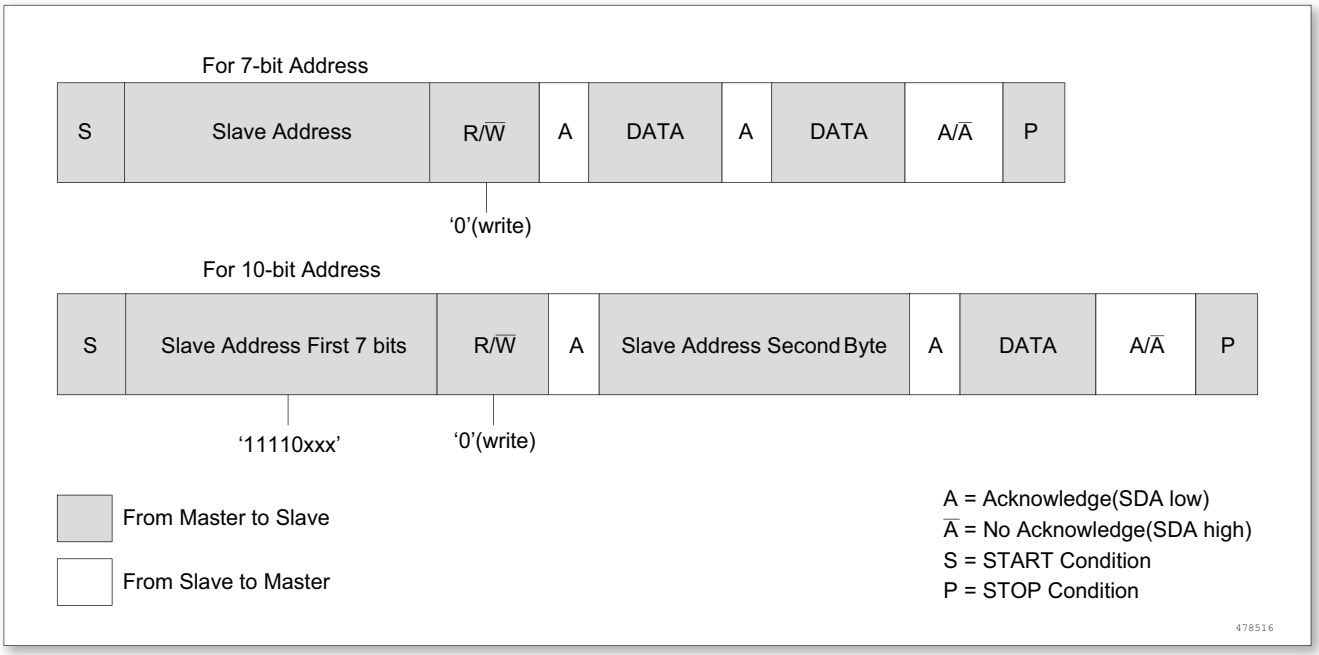

Figure 215. Master Transmitting Protocol

Master receiver and slave transmitter

When the master receives the data, as shown in the figure below, the master shall respond to the slave transmitter after receiving data of one byte, except for the last byte. In this way, the master receiver sends signal indicating whether it is the last byte to the slave transmitter. The slave transmitter shall release the SDA when detecting a NACK so that the master generates a Stop condition.

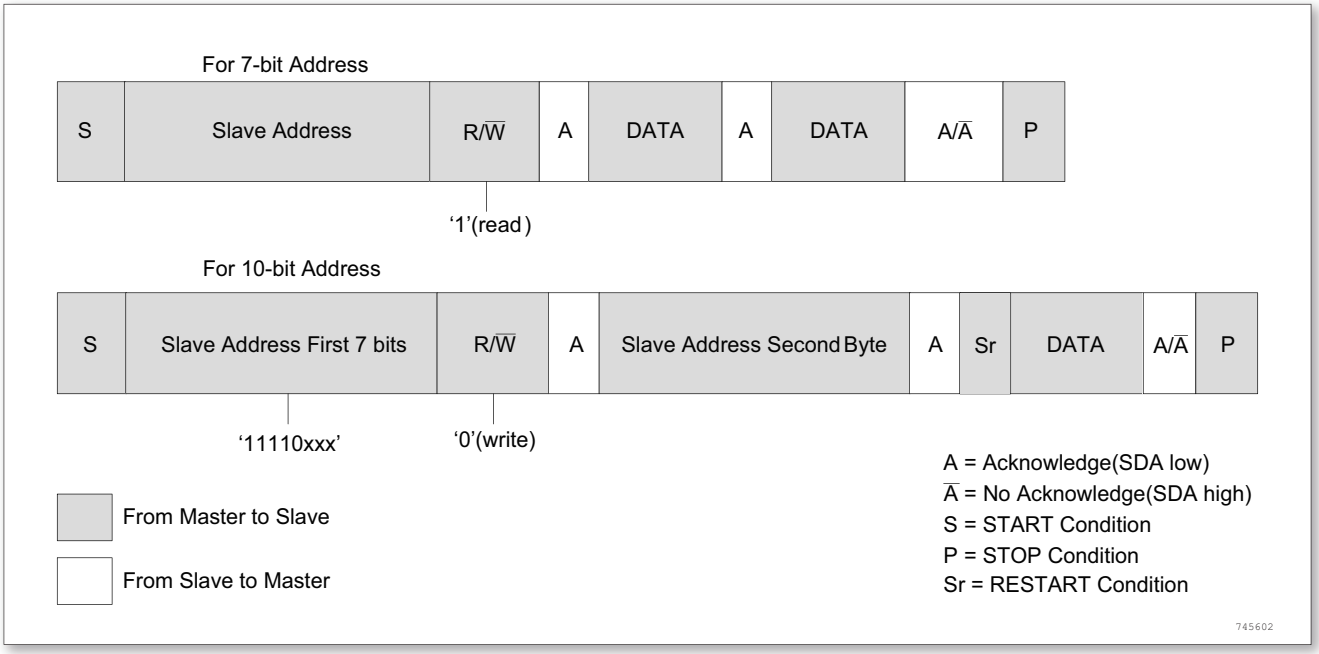

Figure 216. Master Receiving Protocol

When the master needs not to generate Stop conditions, to release the bus, a repeated Start condition can be generated, which is the same as the Start condition except that it is generated after the ACK. In the master mode, the I2C interface communicates with the same slave using different directions of transmission.

Start byte transmission protocol

The start byte transmission protocol is used by systems without dedicated I2C hardware module. When the I2C module is used as the master, the start byte output can be generated for the required slave at the beginning of each transfer.

The protocol consists of seven 0s and one 1, as shown in the following figure. The processor enables inquiring the bus with a low speed sampling flag 0 during the address phase. Once 0 is detected, the processor switches from the low-speed sampling mode to the normal-speed mode of the master.

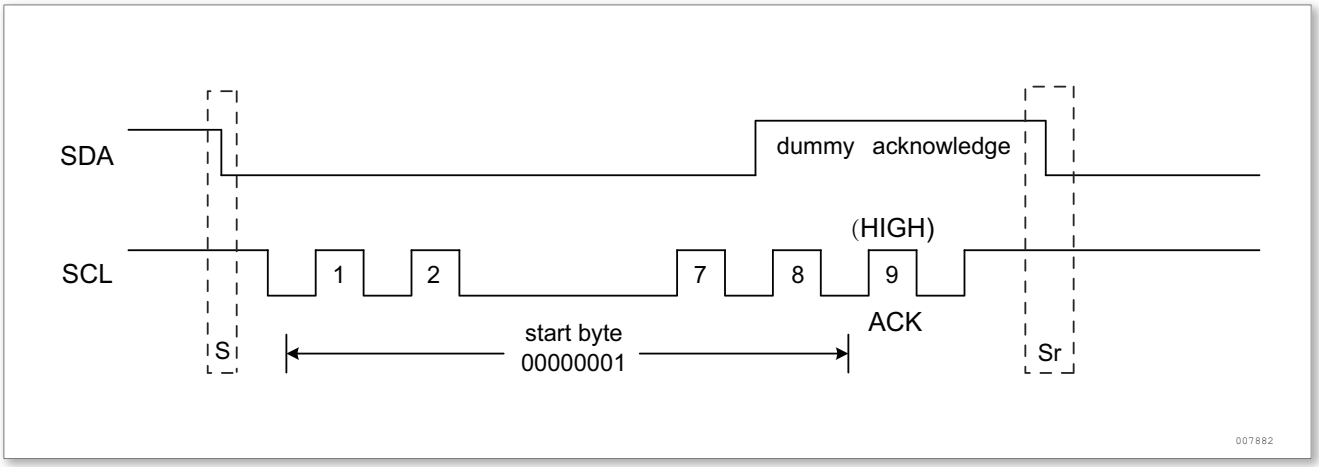

Figure 217. Start Byte Transmission

The start byte procedure is as follows:

1. The master generates a starting condition
2. The master sends the start byte (0000 0001)
3. The master sends an ACK clock pulse (ACK)
4. No slave responds to the ACK signal
5. The master generates a repeated Start condition (RESTART)

The hardware I2C receiver needs not to respond to the start byte since it is a reserved address and the address is reset after RESTART.

19.3.4 Transmitting buffer management and generation of Start, Stop, and repeated Start conditions

In the master mode, the I2C module generates a Stop condition on the bus whenever the transmitter is null. If the repeated Start condition generation is enabled (RESTART = 1), a repeated Start condition is generated when the transfer direction changes from read to write or from write to read. If the repeated Start condition is disabled, a Start condition will be generated after the Stop condition.

The figure below shows the bits of the DR register.

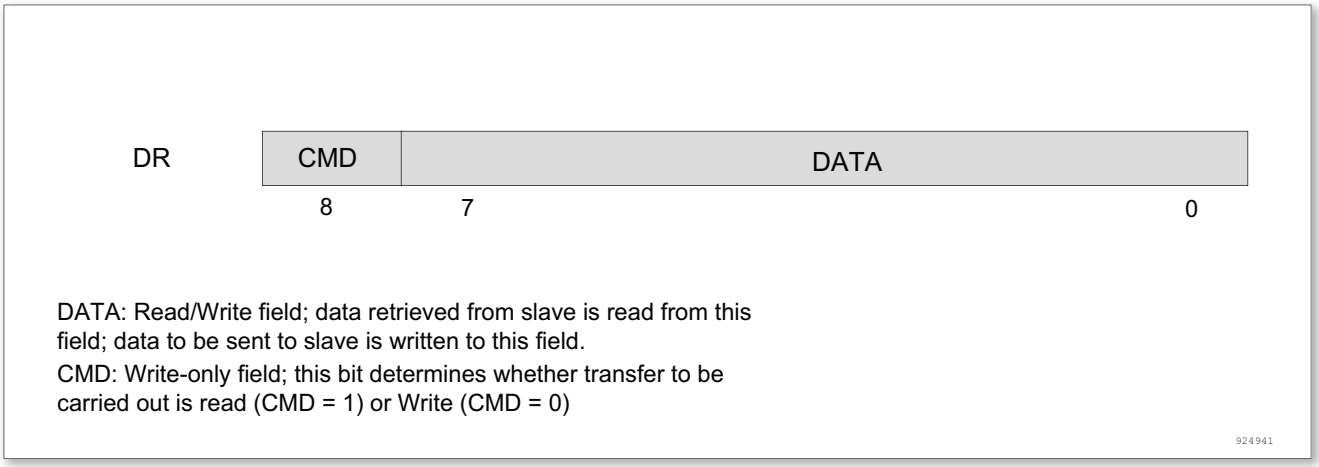

Figure 218. DR Register

The timing diagram below describes the behavior of the I2C module in the master transmitting mode when the Tx FIFO becomes null.

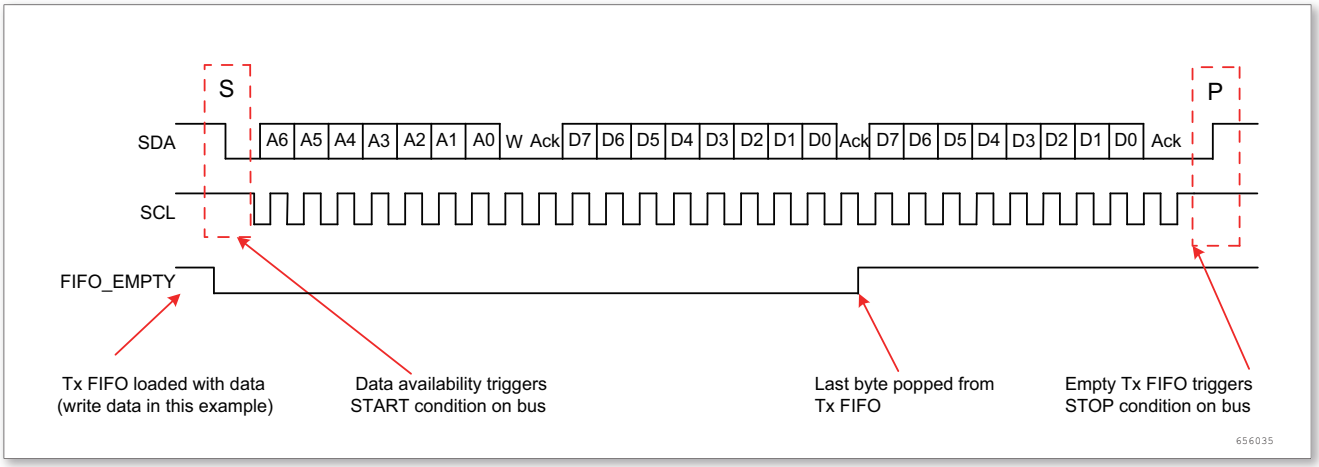

Figure 219. Master Transmitting - Null Tx FIFO

The timing diagram below describes the behavior of the I2C module in the master receiving mode when the Tx FIFO becomes null.

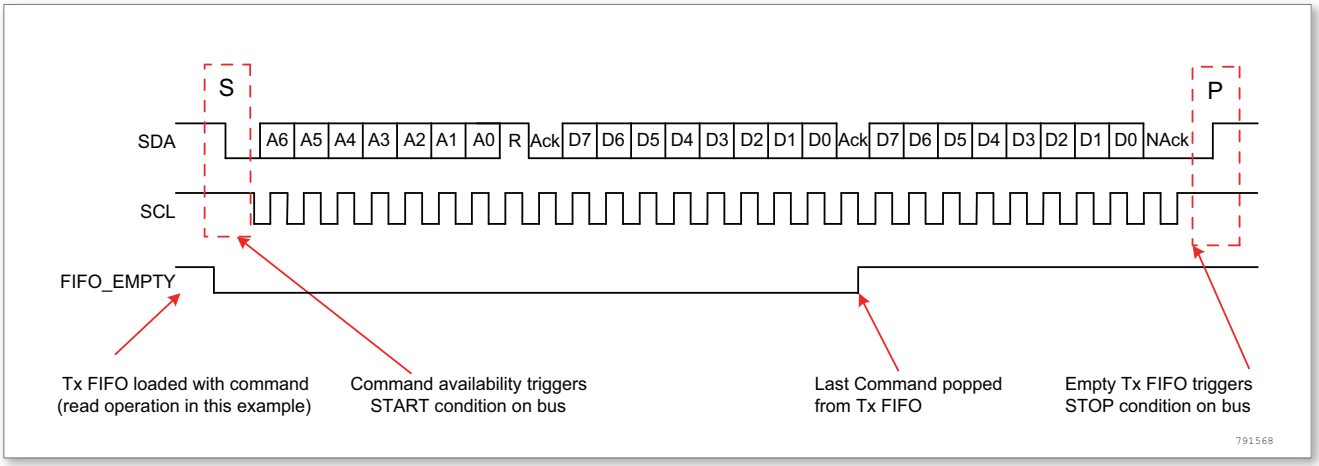

Figure 220. Master Receiving - Null Tx FIFO

19.3.5 Multiple-master arbitration

The I2C bus is a multi-master bus. Arbitration is a process that multiple masters simultaneously attempt to control the bus, but only one of them is allowed to control the bus and the message is not damaged. Once one of the masters has controlled the bus, the other master can not control the bus until the master sends a Stop condition and sets the bus to the idle state.

Arbitration occurs on the SDA when the SCL line is high. If two or more masters attempt to send information to the bus, and if the other master generates a ”0”, the master that first generated a ”1” will lose the arbitration. Those that lost the arbitration continue to generate clock pulses until the end of the byte transfer. If each master attempts to address the same device, arbitration will continue during the data phase.

After detecting the arbitration lost, the I2C interface stops generating the SCL signal.

The following figure shows the bus timing for arbitration of two masters

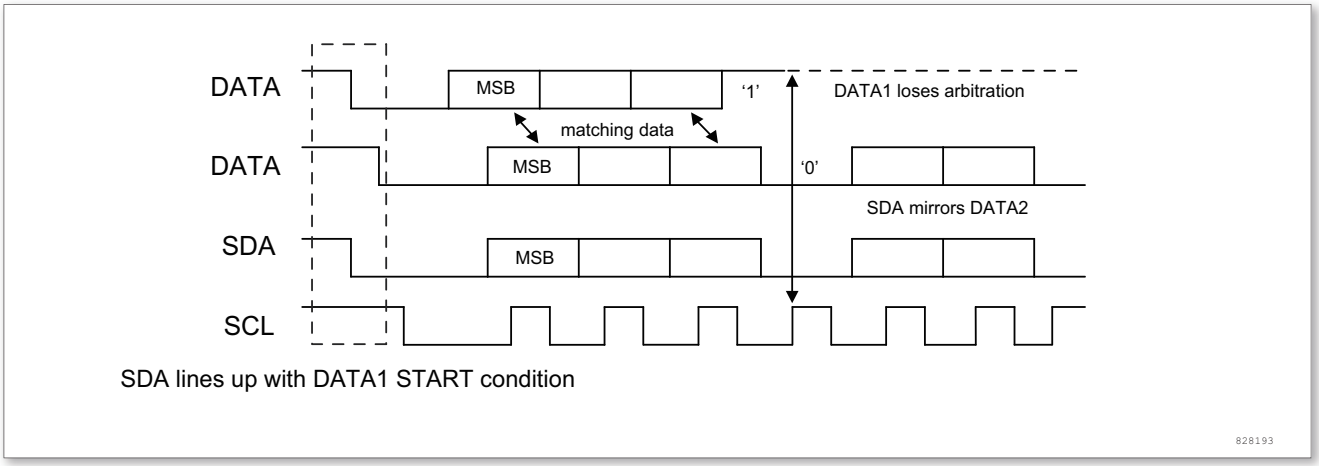

Figure 221. Multiple-master Arbitration

19.3.6 Clock synchronization

When two or more masters attempt to transmit information on the bus simultaneously, they must arbitrate and synchronize the SCL clock. All masters generate their own clocks to transmit messages. The data is only active when the clock is high. Clock synchronization is achieved with ’AND’ connection of the SCL signal. When the master turns the SCL clock to 0, the master will calculate the SCL low time and set the SCL clock to 1 at the beginning of next clock cycle. However, the master will enter a wait state until the SCL clock changes to 1 if another master keeps SCL at 0.

All masters will calculate their high time, and those with the shortest high time will change SCL to 0. Then, the master will calculate the low time, and those with the longest low time will force other masters to enter the wait state, generating a synchronized SCL clock, as shown in the following figure.

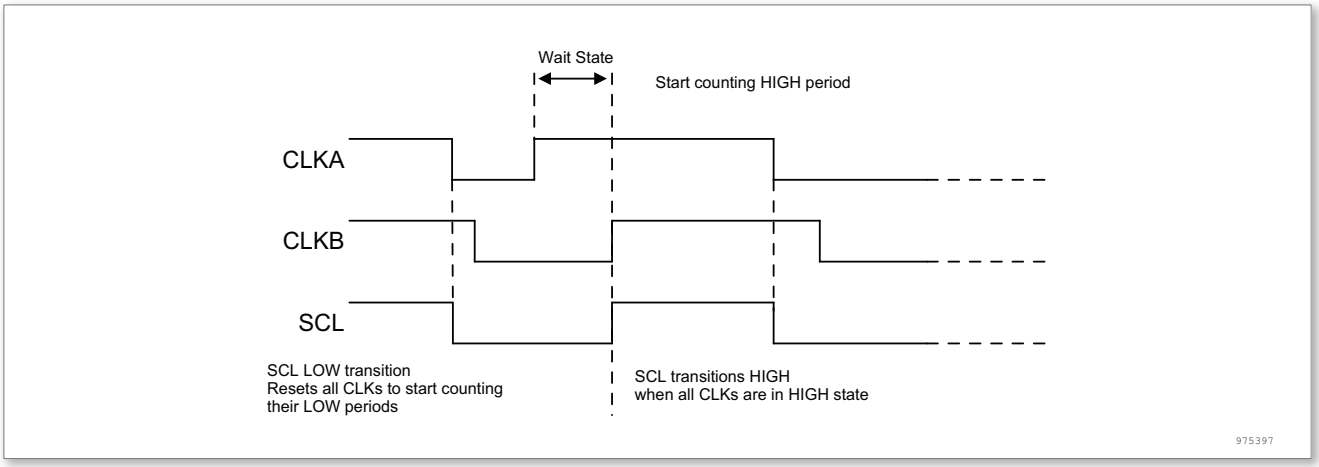

Figure 222. Clock Synchronization of Multiple Masters

19.4 I2C operating mode

The I2C interface operates in one of four modes:

- Slave transmitter mode
- Slave receiver mode
- Master transmitter mode
- Master receiver mode

Note: The I2C interface module can only operates in either master mode or slave mode, and not in both modes at the same time. Therefore, Bit 6 (DISSLAVE) and Bit 0 (MASTER) in register CR shall not be set to 0 and 1 respectively (or 1 and 0 respectively).

The functional block diagram of I2C is as follows:

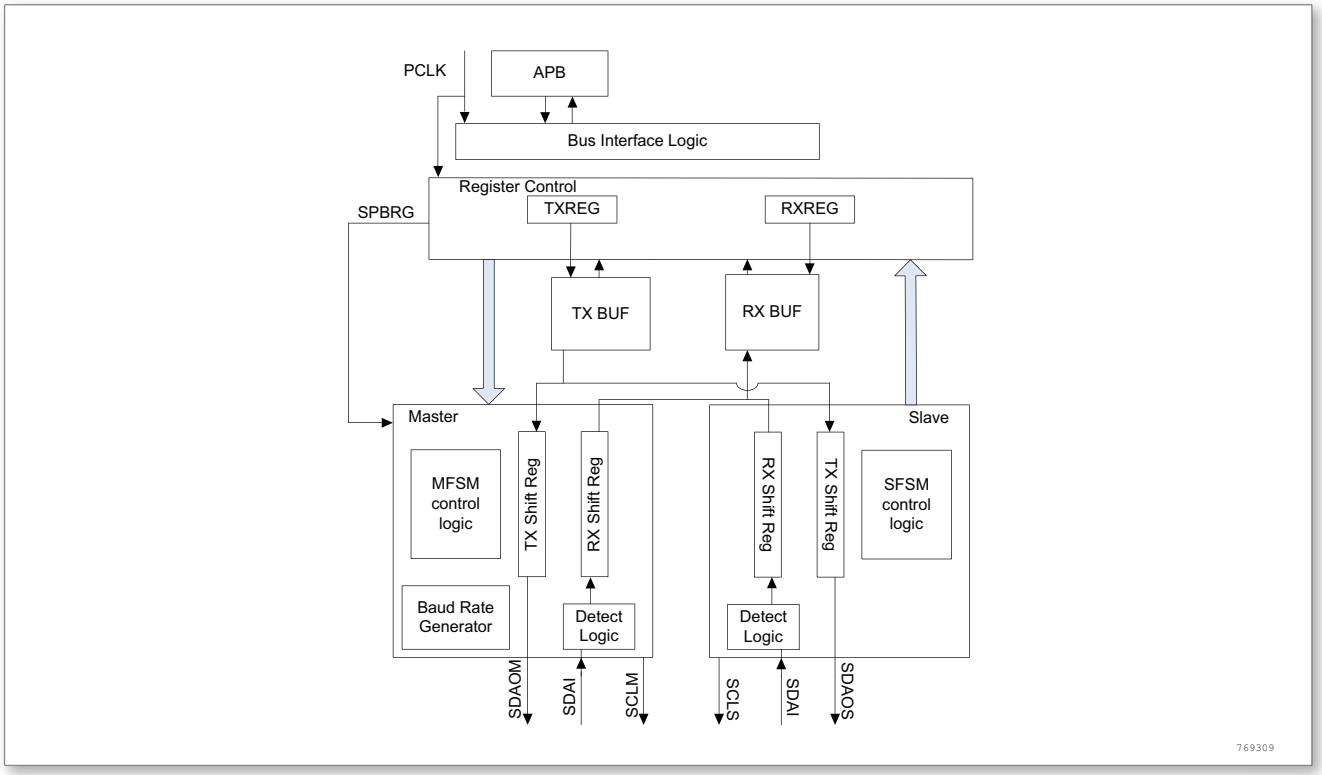

Figure 223. I2C Functional Block Diagram

19.4.1 Slave mode

The following describes the procedure flow chart of the slave mode

Initial configuration

1. Write 0 to Bit 0 of ENR register, to disable I2C.
2. Configure the slave address by initializing the SAR register. The address is that the I2C interface responds to.
3. Configure the specified address format of CR register (set bit 3 to select the 7-bit or 10-bit address format). Write 0 to Bit 6 of the CR register (DISSLAVE) and write 0 to bit 0 (MASTER).
4. Write 1 to bit 0 in the ENR register, enabling the I2C interface module.

Single byte operation of slave transmitter

When the I2C interface is addressed by another I2C master and requests data, the I2C interface operates in the slave transmitter mode as follows:

1. Other I2C master devices initialize the I2C transfer, with the transmit address matching the slave address in the SAR register.
2. The I2C interface responds to the address sent, identifying the transmission direction is in the slave transmitter mode.
3. The I2C interface generates the RD_REQ interrupt (Bit 5 of Register RAWISR) and sets the SCL line low. The bus is always in waiting state until the software responds.

If the RD_REQ interrupt is masked (register IMR5 = 0), it is recommended that the CPU

periodically inquires the RAWISR register.

1. Setting bit 5 of RAWISR is equivalent to generating an RD_REQ interrupt.
2. The software shall meet the requirements for I2C transmission.
3. The time interval is usually around 10 SCL clock cycles. For example, at 400 kbps, the time interval is 25 us.
4. If the Tx FIFO is still loaded with data before receiving a read request, the I2C interface will generate a TX_ABRT interrupt (RAWISR6) and clear the data in the Tx FIFO.
5. The software writes the data to the DR register (its bit 8 is set to 0).
6. Software shall first clear RD_REQ and TX_ABRT interrupts in the RAWISR registers (bits 5 and 6 respectively)
7. The I2C interface releases SCL and sends a data byte.
8. The master device sends a repeated Start condition, to control the bus, or sends a Stop condition to release the bus.

Single byte operation of slave receiver

When the I2C interface is addressed by other master devices and data is sent, the I2C interface operates in the slave receiver mode, as follows:

1. Other I2C master devices initialize the I2C transfer, with the transmit address matching the slave address in the SAR register.
2. The I2C interface responds to the address sent, identifying the transmission direction is in the slave receiver mode.
3. The I2C interface receives the data sent by the master and stores it in the receive buffer.
4. The I2C interface generates an RX_FULL interrupt (RAWISR2). If the RX_FULL interrupt is masked (IMR2 = 0), it is recommended that the software periodically inquire the SR register. When bit 3 of SR register (RFNE) is 1, it is equivalent to the RX_FULL interrupt generated.
5. The software obtains the received data by reading bit 7:0 in the DR register.
6. The master device sends a repeated Start condition, to control the bus, or sends a Stop condition to release the bus.

Block transmission of slave

In the standard I2C protocol, all data is processed in single byte, and the program responds to the master's read request by writing a byte to the slave's Tx FIFO. When a slave (salve transmitter) receives a read request (RD_REQ) from the master (master receiver), at least one data is sent to the Tx FIFO of slave transmitter. This I2C interface module enables processing multiple data in the x FIFO, therefore, for the next read request, an interrupt is not needed to fetch data, thus greatly reducing the waiting time caused by each data interruption.

This mode only acts when the I2C interface is in slave transmitter mode. If the master transmitter responds to the data transferred by the slave transmitter, there is no data in the slave's TX FIFO; the I2C interface will set the SCL line of the I2C bus low until the read request interrupt (RD_REQ) is generated and the TX FIFO data is ready before releasing

the SCL line.

If the RX_REQ interrupt is masked (ISR5 = 0), the software can periodically inquire and read RAWISR register. When reading RAWISR5, returning to 1 is equivalent to generating the RX_REQ interrupt.

The RD_REQ interrupt is generated due to the read request, like an interrupt, it must be cleared when exiting the Interrupt Service Routine (ISR). One or more bytes of data can be written to the TX FIFO in an Interrupt Service Routine (ISR). In the process of transferring these bytes to the master, if the master responds to the last byte, the slave must generate the RD_REQ interrupt request again. This is because that the master requires more data.

If the master receives n bytes from the I2C interface, but the number of data written to the Tx FIFO by the program is greater than n, the slave will clear the Tx FIFO and ignore the extra words after transmitting data of required n bytes.

19.4.2 Main mode

Initial configuration

1. Disable the I2C interface by setting ENR0 = 0
2. Configure bit 2:1 of the CR register, to set the rate mode (standard mode and fast mode) for I2C operation. In addition, ensure bit 6 (DISSLAVE) is 1, and bit 0 (MASTER) is 1.
3. Write the I2C device address to the TAR register. Set this register, which can be configured as a broadcast address or start byte command.
4. Set ENR0, to enable the I2C interface.
5. Write the transferred data and the transfer direction to the DR register. If the DR register is configured before the I2C interface is enabled, data and commands will be lost since the buffer is cleared when the I2C interface is disabled.

By following the above steps, I2C interface will generate a Start condition and send the address byte data to the I2C bus.

Master transmitter and master receiver

The I2C interface supports dynamic switching of reads and writes. When transmitting data, write data to the lower byte (DR) of the I2C RX/TX data buffer and command register, and set the CMD bit to 0, to allow a write operation. For the next read command, it is unnecessary to set the low byte of the DR register, and the CMD bit shall be 1. If the transmitter's FIFO is null, the I2C module sets SCL low until the next command is written to the transmitter's FIFO.

Program flow chart

The following flow chart is a program example of the I2C interface used as a master:

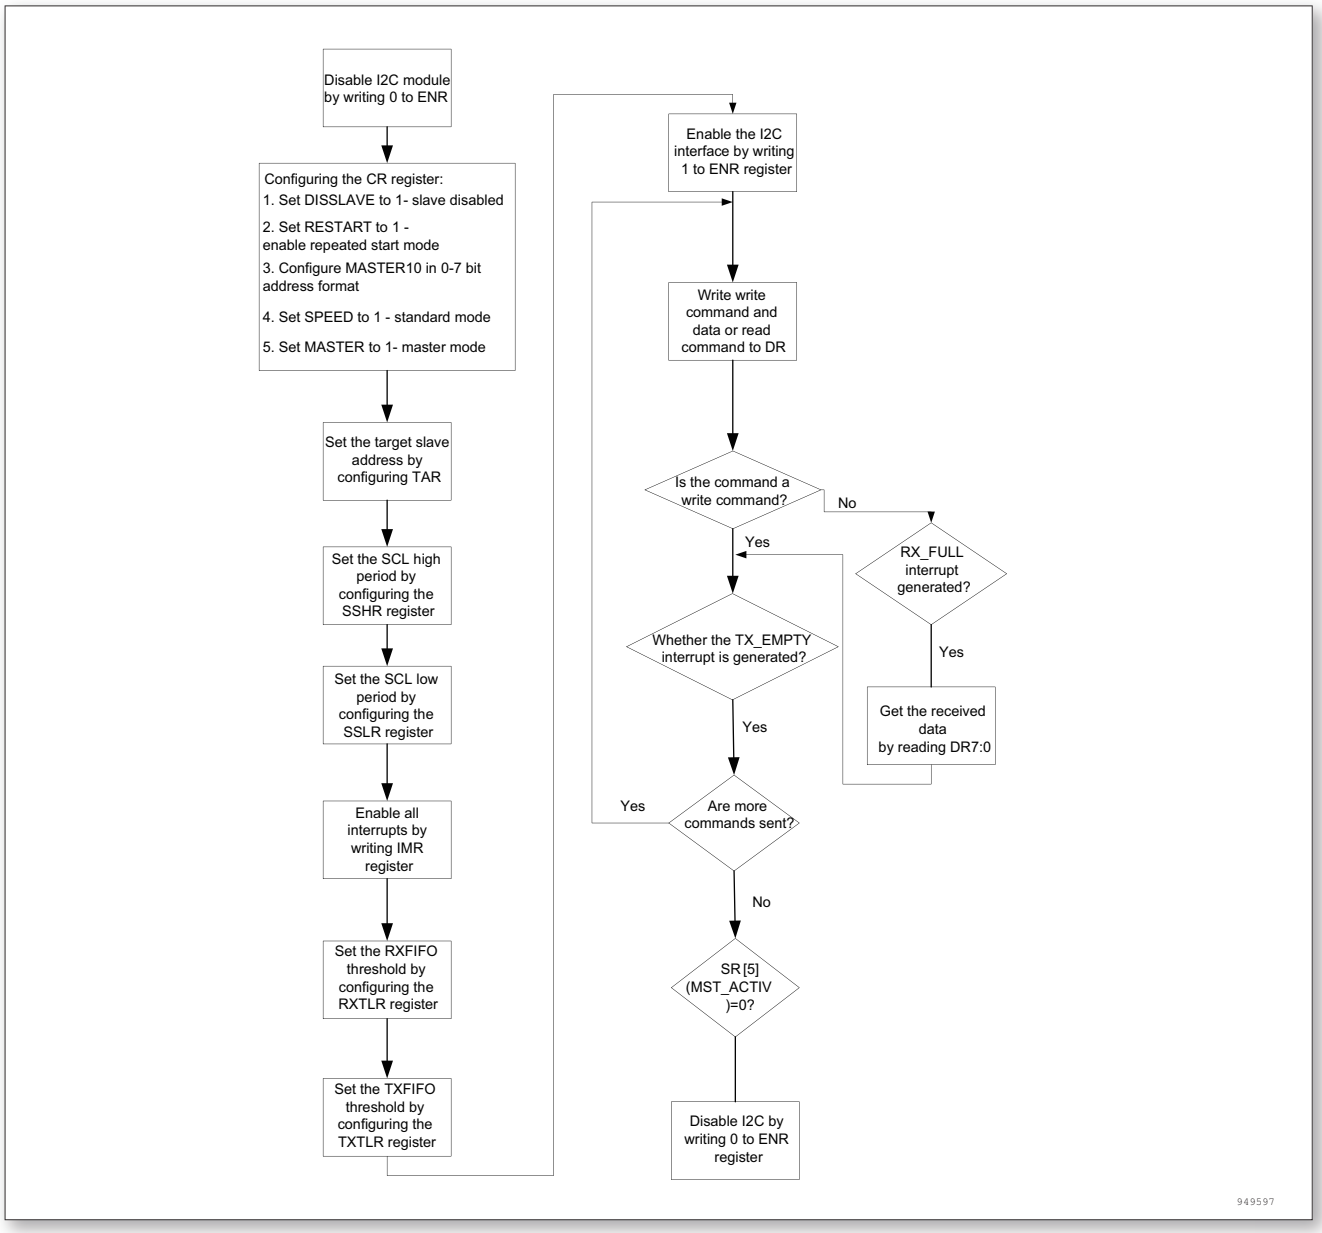

Figure 224. Flow Chart of I2C Interface Master

19.4.3 I2C abort transmission

The ABRT control bit in the ENR register allows the software to disable the I2C bus before transmitting the command in the TX FIFO. In response to the ABORT request, the I2C module issues a Stop condition to the I2C bus while clearing the TX FIFO. The transfer of operation value can be aborted in the master mode.

Procedure

1. Stop writing new commands to the Tx FIFO (DR)
2. Disable the transmission of DMA by setting TDMAE = 0 when operating in DMA mode
3. Set the ABRT bit of ENR register to 1
4. Wait for TX_ABRT interrupt

19.5 Communication using DMA

The I2C interface supports data transmission and reception through DMA, namely, DMA transmission or DMA reception can be enabled separately by setting the corresponding bit in the DMA register. A DMA request will be generated when the data register becomes null during the transmission or becomes full upon reception. The DMA request must be acknowledged before the end of the current byte transfer.

Transmission using DMA

DMA mode can be enabled for transmission by setting the TXEN bit in the DMA register. Data will be loaded from a Memory area predefined to the DR register during data transfer.

Reception using DMA

DMA mode can be enabled for reception by setting the RDMAE bit in the DMA register. Data will be loaded from the DR register to a Memory area predefined during each data reception after DMA channel is configured by I2C.

19.6 I2C interrupt

The following table lists the I2C interrupt bits and how they are set and cleared. Some bits are set by hardware and cleared by software; the other bits are set and cleared by hardware.

Table 60. Set and Clear Interrupt Bits

Interrupt bit	Set by hardware/cleared by software	Set and cleared by hardware
GEN_CALL	√	x
START_DET	√	x
STOP_DET	√	x
ACTIVITY	√	x
RX_DONE	√	x
TX_ABRT	√	x
RD_REQ	√	x
TX_EMPTY	x	√
TX_OVER	√	x
RX_FULL	x	√
RX_OVER	√	x
RX_UNDER	√	x

The following figure depicts that interrupt bits in the interrupt register are set by hardware and cleared by software.

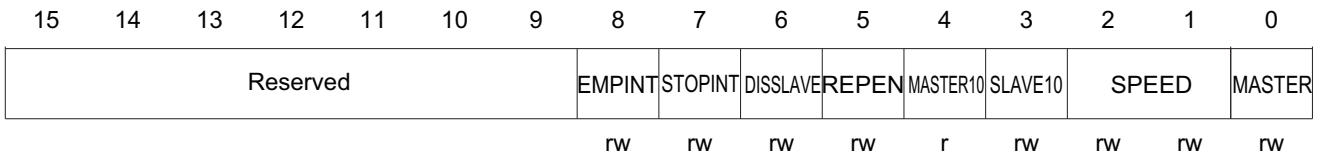
19.7.1 I2C control register(I2C_CR)

Offset address: 0x00

Reset value: 0x0011



Bit	Field	Type	Reset	Description
15 : 9	Reserved			Always read as 0.
8	EMPINT	rw	0x00	This bit controls the generation of TX_EMPTY interrupt. Refer to the IC_RAW_INTR_STAT register for details.
7	STOPINT	rw	0x00	In the slave mode, whether a STOP_DET interrupt is generated. 1: STOP_DET interrupt is generated when the address matches 0: STOP_DET interrupt is generated regardless of the address match. This bit is only applicable to slave mode. Note: During the addressing of broadcasting address, if this bit is set, the slave will not generate a STOP_DET interrupt. The STOP_DET interrupt is generated only when the transmitted address matches the slave address.

Bit	Field	Type	Reset	Description
6	DISSLAVE	rw	0x00	This bit controls whether I2C has its slave disabled 0: Slave enabled 1: Slave disabled
5	REPEN	rw	0x00	Determines whether RESTART conditions may be sent when acting as a master 0: Disabled 1: Enabled When RESTART is disabled, the following functions cannot be performed when the I2C interface acts as a master: Send start byte Change the transmission direction in combined format mode Read data 10-bit address format The RESTART condition is replaced by sending a Stop condition first and then transmitting a Start condition. If the above operation is executed, bit 6 (TX_ABRT) of the IC_RAW_INTR_STAT register is set.
4	MASTER10	r	0x01	Address mode when acting as a master 0: 7-bit address format 1: 10-bit address format
3	SLAVE10	rw	0x00	When acting as a slave, this bit controls whether the I2C re- sponds to 7- or 10-bit addresses 0: 7-bit addressing address. The I2C interface ignores 10-bit addressing. For 7-bit addressing, only the lower 7 bits of IC_SAR register is compared. 1: 10-bit addressing address. I2C only responds to 10-bit addressing; the receiving address is compared with 10 bits of IC_SAR.
2 : 1	SPEED	rw	0x00	These bits control at which speed the I2C operates This configuration is only valid when the I2C interface operates in the master mode. 1: Standard mode (0 ~ 100 Kbps) 2: Fast mode (400 Kbps)
0	MASTER	rw	0x01	This bit controls whether the I2C master is enabled 0: Master disabled 1: Master enabled

The DISSLAVE (bit 6) and MASTER (bit 0) configurations are listed in the following table:

Table 62. DISSLAVE (Bit 6) and MASTER (Bit 0) Configurations

DISSLAVE CR[6]	MASTER CR[0]	Status
0	0	Slave device

DISSLAVE CR[6]	MASTER CR[0]	Status
0	1	Configuration error
1	0	Configuration error
1	1	Master device

19.7.2 I2C destination address register(I2C_TAR)

Offset address: 0x04

Reset value: 0x0055

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved				SPECIAL	GC	ADDR									
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit	Field	Type	Reset	Description
15 : 12	Reserved			Always read as 0.
11	SPECIAL	rw	0x00	This bit indicates whether the software executes a special command (general call or start byte command) 0: Ignore the 10-bit GC, and use the ADDR bit normally 1: Execute special I2C commands such as GC bit
10	GC	rw	0x00	If bit 11 (SPECIAL) is set to 1, then this bit indicates whether a General Call or START byte command is to be performed by the I2C 0: General call address. Only perform write operation when sending a general call address. The I2C interface always operates in broadcast address mode until SPECIAL (bit 11) is cleared. 1: Start byte command
9 : 0	ADDR	rw	0x55	This is the target address for any master transaction When a broadcast address is sent, these bits can be ignored. To generate the start byte command, the CPU only needs to write these bits once.

19.7.3 I2C slave address register(I2C_SAR)

Offset address: 0x08

Reset value: 0x0055

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved						ADDR									
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit	Field	Type	Reset	Description
15 : 10	Reserved			Always read as 0.
9 : 0	ADDR	rw	0x55	When the I2C interface operates in the slave mode, for slave memory address in 7-bit address format, ADDR [6:0] is only valid.

19.7.4 I2C data command register(I2C_DR)

Offset address: 0x10

Reset value: 0x0001

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved					RESTART	STOP	CMD	DAT							
					w	w	w	rw	rw	rw	rw	rw	rw	rw	rw

Bit	Field	Type	Reset	Description
15 : 11	Reserved			Always read as 0.
10	RESTART	w	0x00	Whether to generate a RESTART signal before transmission or reception This bit is only valid when IC_EMPTYFIFO_HOLD_MASTER_EN is set to '1' 1: If the RESTART signal is "1", the data is received or sent (according to a RESTART signal will be generated before data reception or transmission (depending on CMD), regardless of the previous command changes the direction of data transmission. If IC_RESTART_EN signal is set to '0', the STOP signal will follow the START signal 0: If the RESTART signal is set to '1', the RESTART signal is generated only when the previous command changes the direction of data transmission. If the RESTART signal is set to '0', the STOP signal will follow the START signal

Bit	Field	Type	Reset	Description
9	STOP	w	0x00	STOP: Whether to generate a STOP signal after transmission or reception This bit is only valid when IC_EMPTYFIFO_HOLD_MASTER_EN is set to '1' 1: A STOP signal is generated after the current byte, regardless of the Tx FIFO is null. If he Tx FIFO is not null, the master immediately issues a new transmission and bus arbitration signal. 0: A STOP signal is not generated after the current byte, regardless of the Tx FIFO is null. The master continues the current transmission (data transmission or reception depending on CMD). If the Tx FIFO is null, the master will set SCL low, to pend the bus until Tx FIFO receives new data
8	CMD	w	0x00	Control read or write operations in master mode 1: Read 0: Write When a command is sent to TX FIFO, this bit is used to distinguish between read and write commands. In the slave receiver mode, the write operation of this bit is ignored. In the slave transmitter mode, writing 0 indicates that the data of the DR register is ready to be sent.
7 : 0	DAT	rw	0x01	I2C bus data to be sent or received

19.7.5 Standard mode I2C clock high counter register(I2C_SSHR)

Offset address: 0x14

Reset value: 0x0190

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CNT															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit	Field	Type	Reset	Description
15 : 0	CNT	rw	0x0190	SCL clock high period in standard mode of I2C interface Note: This register has a configurable value between 6 and 65525. This is because the I2C interface uses a 16-bit counter; the I2C bus is in the idle state when the counter value is SSHR + 10.

19.7.6 Standard mode I2C clock low counter register(I2C_SSLR)

Offset address: 0x18

Reset value: 0x01D6

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CNT															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit	Field	Type	Reset	Description
15 : 0	CNT	rw	0x01D6	The minimum SCL clock low period is 8 in the I2C interface standard mode.

19.7.7 Fast mode I2C clock high counter register(I2C_FSHR)

Offset address: 0x1C

Reset value: 0x0036

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CNT															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit	Field	Type	Reset	Description
15 : 0	CNT	rw	0x0036	SCL clock high period in fast mode of I2C interface This register is read-only and returns 0 when I2C operates in standard mode, with the minimum value of 6.

19.7.8 Fast mode I2C clock low counter register(I2C_FSLR)

Offset address: 0x20

Reset value: 0x0082

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CNT															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit	Field	Type	Reset	Description
15 : 0	CNT	rw	0x0082	SCL clock low period in fast mode of I2C interface This register is read-only and returns 0 when I2C operates in standard mode, with the minimum value of 8.

19.7.9 I2C interrupt status register(I2C_ISR)

Offset address: 0x2C

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved		D	RESTART	GC	START	STOP	ACTIV	RX_DONE	TX_ABRT	RD_REQ	TX_EMPTY	TX_OVER	RX_FULL	RX_OVER	RX_UNDER
		r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bit	Field	Type	Reset	Description
15 : 14	Reserved			Always read as 0.
13 : 0	ISR	r	0x0000	Refer to the RAWISR register for specific description of each bit

19.7.10 I2C interrupt mask register(I2C_IMR)

Offset address: 0x30

Reset value: 0x08FF

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved				GC	START	STOP	ACTIV	RX_DONE	TX_ABRT	RD_REQ	TX_EMPTY	TX_OVER	RX_FULL	RX_OVER	RX_UNDER
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit	Field	Type	Reset	Description
15 : 12	Reserved			Always read as 0.
11 : 0	IMR	rw	0x08FF	Each bit is masked and mapped to the ISR.

19.7.11 I2C RAW interrupt register(I2C_RAWISR)

Offset address: 0x34

Reset value: 0x0000

The difference between RAWISR and ISR registers is that the former is not masked.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved				GC	START	STOP	ACTIV	RX_DONE	TX_ABRT	RD_REQ	TX_EMPTY	TX_OVER	RX_FULL	RX_OVER	RX_UNDER
				r	r	r	r	r	r	r	r	r	r	r	r

Bit	Field	Type	Reset	Description
15 : 12	Reserved			Always read as 0.
11	GC	r	0x00	General call This bit is set when a general call address is received. The I2C interface is disabled or cleared when the CPU reads the GC register. I2C stores the received data in the receiver buffer.

Bit	Field	Type	Reset	Description
10	START	r	0x00	Start condition detection Regardless of the I2C interface operates in the master or slave mode, this bit is set once the Start or repeated Start condition is detected on the I2C interface.
9	STOP	r	0x00	Stop condition detection The status of this bit is based on the status of the STOPINT in the CR register when STOPINT = 0 Regardless of the I2C interface operates in the master or slave mode, this bit is set once the Stop condition is detected on the I2C interface.In slave mode, a STOP interrupt is generated regardless of whether the addressing is matched or not. When STOPINT = 1 In master mode (MASTER = 1), this bit shows if a Stop condition occurs on the I2C interface. In slave mode (MASTER = 0), a STOP interrupt is generated only when the slave address is matched successfully.
8	ACTIV	r	0x00	I2C interface is enabled, this bit is used to capture the active state of the I2C module After being set, this bit can only be cleared by the following four methods: Disable I2C interface Read ACTIV register Rread ICR register System reset Once set, this bit can only be cleared by the above method. Even if I2C is idle, this bit also remains high until it is cleared.
7	RX_DONE	r	0x00	Transmit done When I2C is used as a slave transmitter, this bit will be set if the master fails to respond after sending one byte of data. This case happens at the last byte transferred, indicating the end of the transfer.
6	TX_ABRT	r	0x00	Transmit abort When the I2C interface acts as a transmitter, this bit is set if the data in the buffer is failed to be fully sent. Note: The transmit abort bit will clear the receiver and transmitter buffers in the I2C interface. The transmitter buffer is in a refresh state until the TX_ABRT register is read. Once the read operation is performed, the transmitter will receive new data from the APB bus.

Bit	Field	Type	Reset	Description
5	RD_REQ	r	0x00	Read request When I2C acts as a slave, other masters are set when attemptting to read data from the I2C interface. The I2C interface keeps the bus in a wait state (SCL = 0) until the interrupt is processed, which means that the I2C interface is successfully addressed by other masters as a slave and requires data transmission. The processor must respond to the interrupt and then write data to the DR register. This bit is cleared when the processor reads the RD_REQ register.
4	TX_EMPTY	r	0x00	Transmit buffer empty The status of this bit depends on the EMPINT state in the CR register: when EMPINT is 0 and the transmitter buffer is null, this bit is set; when EMPINT is 1, the transmitter buffer is null and the operation of internal shift register is finished, this bit is set This bit is automatically cleared by hardware when the transmitter buffer is not null.
3	TX_OVER	r	0x00	Transmit buffer over If the transmit buffer is full, and the processor writes new data, causing overflow, this bit will be set.
2	RX_FULL	r	0x00	Receive buffer not empty This bit is set when the receive buffer is not null. This bit will be cleared by hardware when the receive buffer is not null.
1	RX_OVER	r	0x00	Receive buffer over This bit will be set when the receive buffer is full and new data is received. The I2C interface will respond at this point, but new data will be lost.
0	RX_UNDER	r	0x00	Receive buffer under This bit will be set when the processor reads the DR register and the RX FIFO is null.

19.7.12 I2C reception threshold(I2C_RXTLR)

Offset address: 0x38

Reset value: 0x0000

20 Universal asynchronous receiver transmitter(UART)

Universal asynchronous receiver transmitter(UART)

20.1 UART introduction

The universal asynchronous receiver transmitter (UART) offers a flexible means of full-duplex data exchange with external equipment requiring an industry standard NRZ asynchronous serial data format. The UART offers a very wide range of baud rates using a fractional baud rate generator. It supports synchronous one-way communication and half-duplex single wire communication as well as modem operations (CTS/RTS).

High speed data communication is possible by using the DMA for multibuffer configuration.

20.2 UART main features

- Support RS-232S protocol in asynchronous mode, and meet Industry Standard 16550
- Support DMA requests
- Full-duplex synchronous operation
- Fractional baud rate generator system
- Programmable baud rate shared by transmitter and receiver
- Separate transmit and receive buffer registers
- Embedded 1 byte transmit and 32 byte receive buffer
- low level first for data transmission and reception
- Starting from start bit, followed by a data bit (the output data length includes 5 bits, 6 bits, 7 bits, 8 bits), and ending with the stop bit. Alternatively, parity check bit is optional, which is set before the stop bit and after the data bit.
- Support hardware odd or even check, generation and detection
- Line break generation and detection
- Support hardware auto flow control
- Support the following interrupt sources:
  - Transmitter BUFFER empty
  - Receiver data valid
  - Receive buffer overflow
  - Frame error
  - Parity error
  - Receive break frame

20.3 UART functional description

At least two pins are required for any UART bidirectional communication: receive data input (RX) and transmit data output (TX).

RX: Receive data serial input. Data is recovered by oversampling techniques, to distinguish between data and noise.

TX: Transmit data output. When the transmitter is disabled, the output pin is returned to its I/O port configuration. The TX pin is high when the transmitter is activated and no data is transmitted.

- The bus shall be idle before transmission or reception
- One start bit
- One data word (5, 6, 7 or 8 bits) with the least significant bit first
- 1 or 2 stop bits, indicating the end of the data frame
- Use the fractional baud rate generator –a representation of 16-bit integers and 4bit decimals

The following pin is required in hardware flow mode:

- nCTS: Clear transmission. If it is high, it blocks the next data transmission at the end of the current data transmission.
- nRTS: Transmit request; the low level indicates that the UART is ready to receive data.

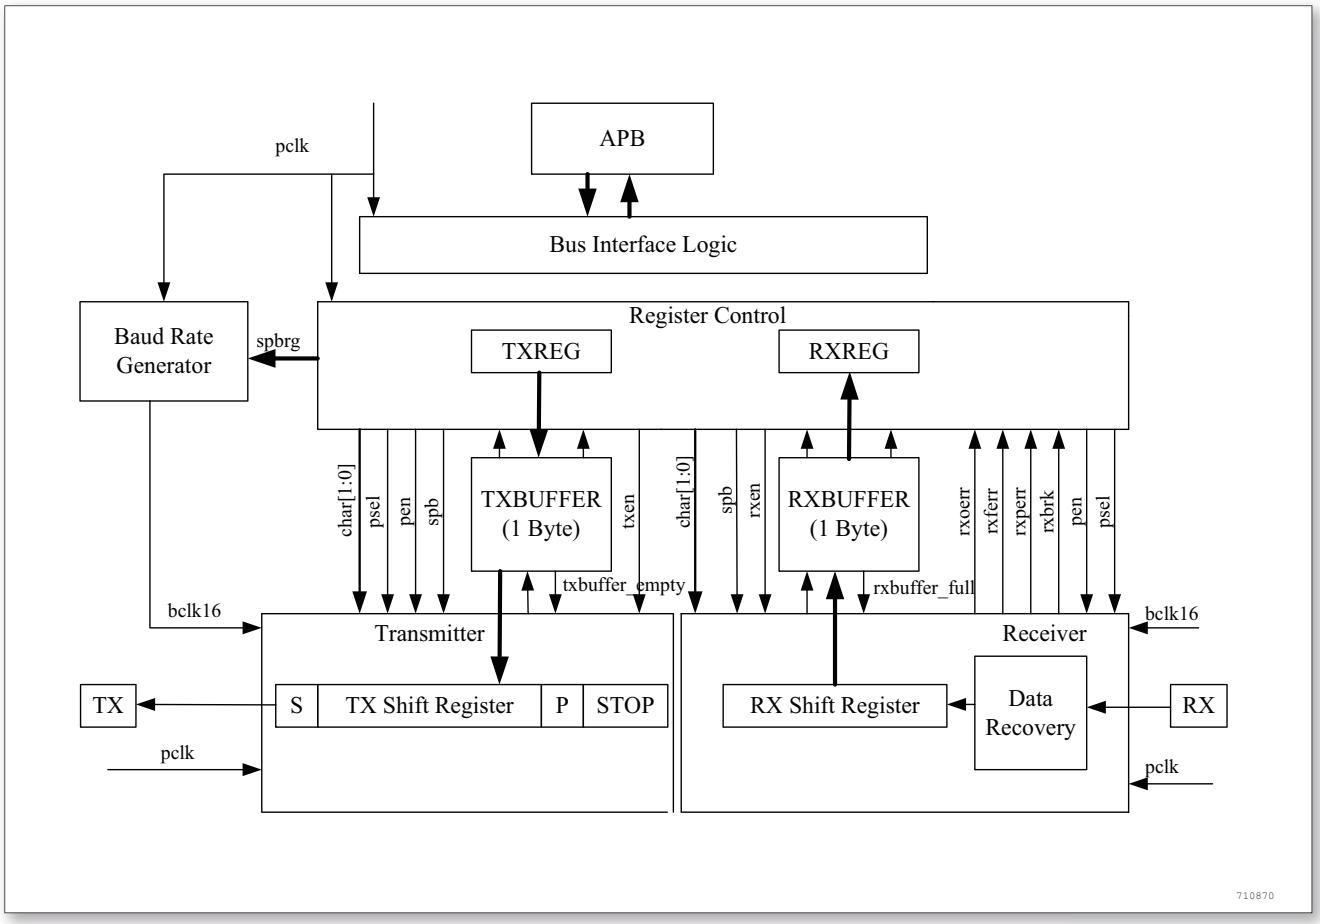

Figure 226. UART Block Diagram

20.3.1 UART character description

Word length may be selected as 5～8 bits by programming the CHAR bit in the UART_CCR register. The TX pin is in low state during the start bit, and is in high state during the stop bit.

An Idle character is interpreted as an entire frame of “1” s followed by the start bit of the next frame which contains data (the number of ‘1’ s will include the number of stop bits).

A Break character is interpreted on receiving ‘0’ s for a frame period. At the end of the break frame the transmitter inserts either 1 or 2 stop bits (logic “1” bit) to acknowledge the start bit.

Transmission and reception are driven by a common baud rate generator; the clock for each is generated when the enable bit is set respectively for the transmitter and receiver.

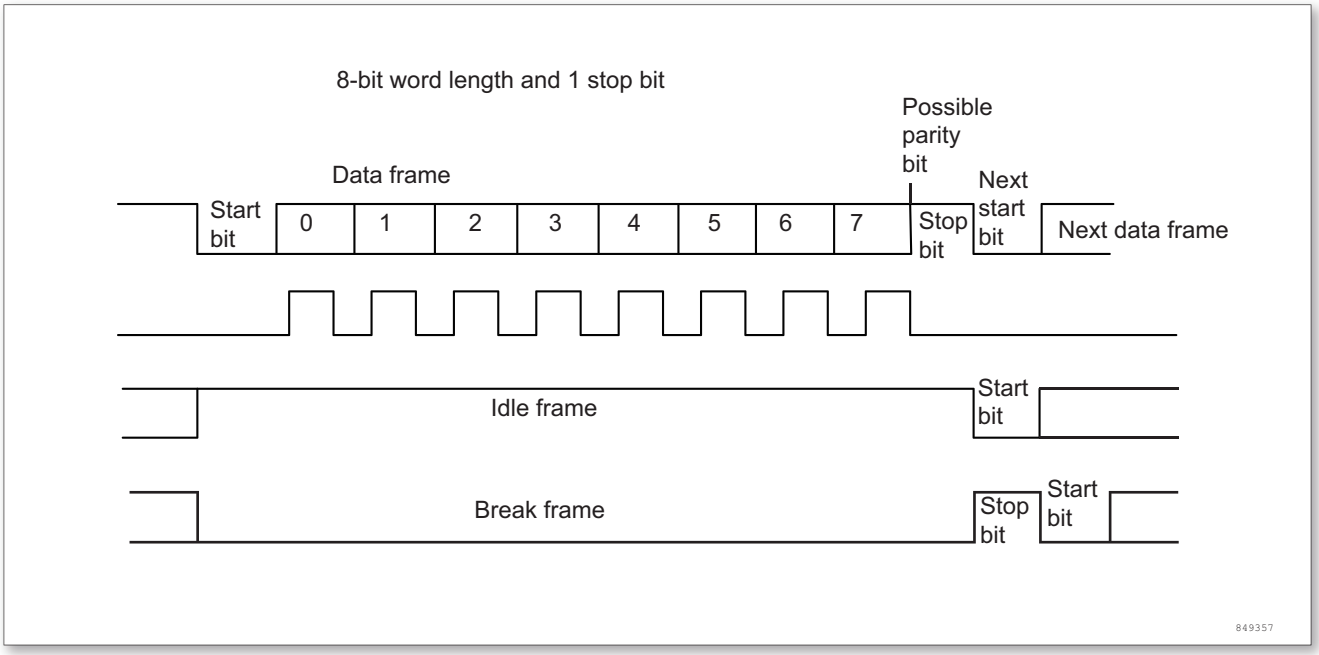

Figure 227. UART Timing

20.3.2 Transmitter

The transmitter can send data words of 5 ~ 8 bits depending on the CHAR bit status. When the transmit enable bit (TXEN) is set, the data in the transmit shift register is output on the TX pin.

Character transmission

During a UART transmission, data shifts out least significant bit first on the TX pin. In this mode, the UART_TDR register consists of a buffer between the internal bus and the transmit shift register.

Every character is preceded by a start bit. The character is terminated by a configurable number of stop bits.

The TXEN bit shall not be reset during transmission of data. Otherwise, the data on the TX pin will be corrupted as the baud rate counters will get frozen, and the current data being transmitted will

be lost.

Configurable stop bits

The number of stop bits to be transmitted with every character can be programmed by setting SPB bits.

A break frame will be 10 low bits followed by the stop bits, or 11 low bits followed by the stop bits.The RXBRK_INTF bit in the interrupt status register will be set when the break frame is received.

Procedure

1. Enable the UART by writing the UARTEN bit in UART_GCR register to 1.
2. Program the CHAR bit in UART_CCR to define the word length.
3. Program the number of stop bits (SPB) in UART_CCR.
4. Set the TXEN bit in UART_GCR.
5. Select the desired baud rate using the UART_BRR register.
6. Write the data to be sent in the UART_TDR register (this clears the TX_INTF bit). Repeat Step 6 for each data to be transmitted in case of single buffer.

Single byte communication

The TX_INTF bit is always cleared by a write to the data register. The TX_INTF bit is set by hardware and it indicates:

- The data has been moved from TDR to the shift register and the data transmission has started.
- The TDR register is cleared.
- The next data can be written in the UART_TDR register without overwriting the previous data.

This flag generates an interrupt if the TXIEN bit is set. When a transmission is taking place in UART, a write instruction to the UART_TDR register stores the data in the TDR register and which is copied in the shift register at the end of the current transmission.

When no transmission is taking place in idle UART, a write instruction to the UART_TDR register places the data directly in the shift register, the data transmission starts, and the TX_INTF bit is immediately set. Meanwhile, TXBUF_EMPTY of UART_CSR is set. If a frame is transmitted (after the stop bit) and no new data is written to UART_TDR (TDR register null), the TXC bit will be set, indicating all transmission has been completed.

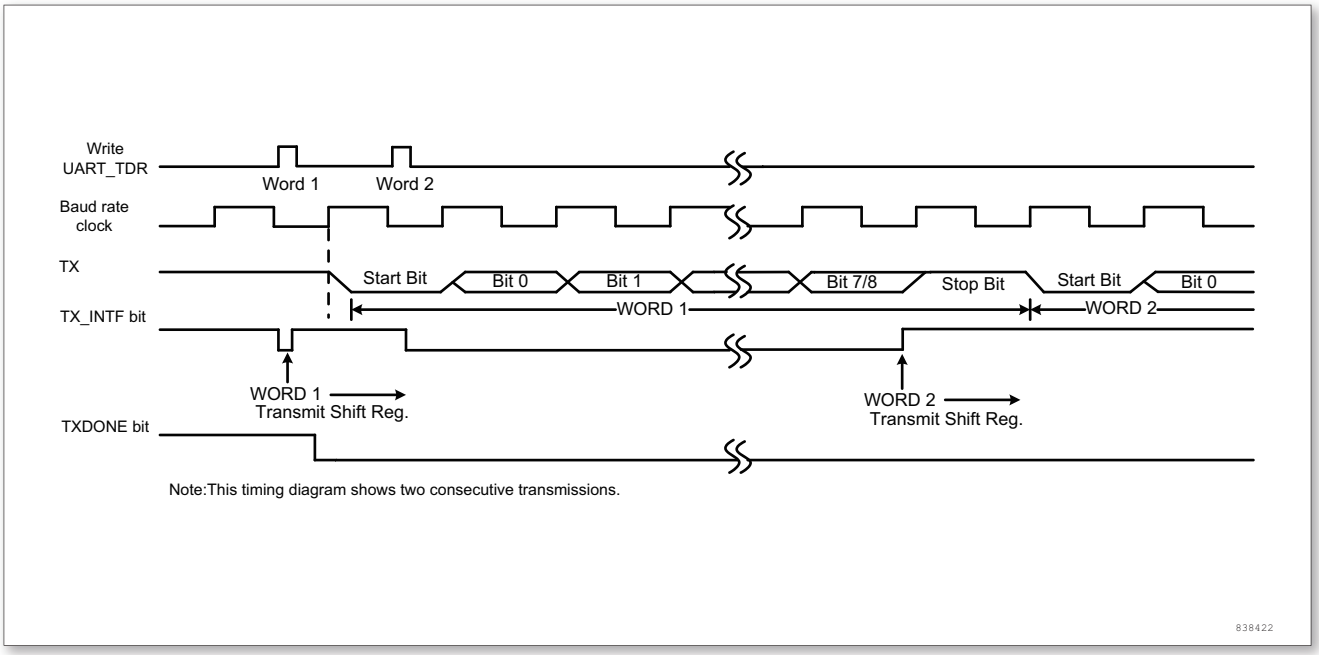

Figure 228. Status Bit Change During Transmission

Break character

Setting the BRK bit transmits a break character. If the BRK bit is set to ’1’, a break character is sent on the TX line after completing the current character transmission. This bit is reset by software when the break character is completed (during the stop bit of the break character). The UART inserts a logic 1 bit at the end of the last break frame, to guarantee the recognition of the start bit of the next frame.

20.3.3 Receiver

Character reception

During a UART reception, data shifts in least significant bit first through the RX pin. In this mode, the UART_RDR register consists of a buffer between the internal bus and the received shift register.

Procedure:

1. Enable the UART by writing the UARTEN bit in UART_GCR register to 1.
2. Program the CHAR bit in UART_CCR to define the word length.
3. Program the number of stop bits (SPB) in UART_CCR.
4. Select the desired baud rate using the UART_BRR register.
5. Set the RXEN bit UART_GCR. This enables the receiver which begins searching for a start bit.

When a character is received:

- The RX_INTF bit is set. It indicates that the content of the shift register is transferred to the RDR. In other words, data has been received and can be read (as well as its associated error flags).
- An interrupt is generated if the RXIEN bit is set.
- The error flags can be set if a frame error or an overrun error has been detected during

reception.

- UART_RDR register is read by software, RX_INTF bit shall be cleared before the next character is received.

The RXEN bit shall not be reset while receiving data. If the RXEN bit is cleared during reception, the current byte to be received will be lost.

Break character

When a break frame is received, the UART is set and RXBRK_INTF interrupt is generated.

Overrun error

An overrun error occurs when a character is received before being read by UART_RDR.

When an overrun error occurs:

- The RXOERR_INTF bit is set.
- The RDR content will not be lost. The previous data is available when a read to UART_RDR is performed.
- The shift register will be overwritten. After that point, any data received will be lost.
- An interrupt is generated if the RXOERREN bit is set.

Frame error

The frame error is detected when the Stop bit is failed to be received and identified, then:

- RXFERR_INTF bit is set by hardware.
- Invalid data will not be transmitted to UART_RDR register from the shift register.
- An interrupt will be generated if RXFERREN bit is set.

20.3.4 Fractional baud rate generator

Set the BRR and FRA registers to set the corresponding baud rate. Refer to the following formula:

$$f_{baudrate} = \frac{f_{PCLK}}{16 \times UARTDIV}$$

$$UARTDIV = BRR + \frac{FRA}{16}$$

Get:

$$f_{baudrate} = \frac{f_{PCLK}}{16 \times BRR + FRA}$$

The BRR register has a minimum value of 4.

20.3.5 Sampling

Since no separate clock is provided for asynchronous operation, the receiver requires synchronization to the receiver. In order to obtain the correct character data on the receive pin 'RX', the UART is configured with a detection circuit. The UART samples the RX pin

through a ’bclk16’ clock with a 16-times data baud rate. Each data has 16 clock samples, and the sampled values of the 7th, 8th, and 9th falling edges are taken.

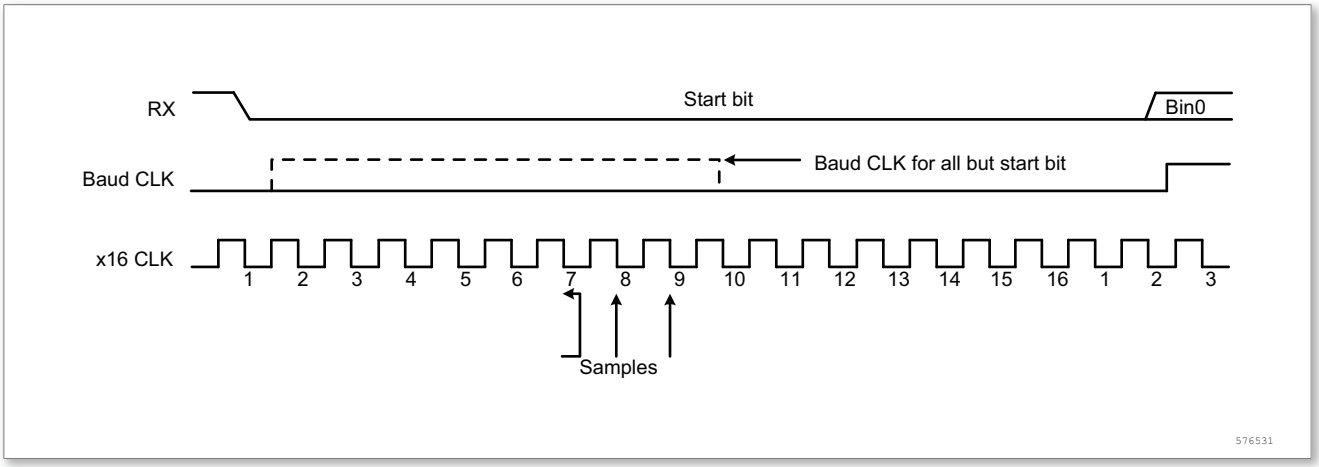

Figure 229. RX Pin Sampling Plan

20.3.6 Parity control

Parity control (generation of parity bit in transmission and parity checking in reception) can be enabled by setting the PEN bit in the UART_CCR register. The invalid data will not be transferred to UART_RDR register from the shift register in case of parity error.

Even parity: the parity bit is calculated to obtain an even number of “1s” inside the frame and the parity bit.

Example: data=00110101; 4 bits set => parity bit will be 0 if even parity is selected (PSEL bit in UART_CCR = 1).

Odd parity: the parity bit is calculated to obtain an odd number of “1s” inside the frame and the parity bit.

Example: data=00110101; 4 bits set => parity bit will be 1 if odd parity is selected (PSEL bit in UART_CCR = 0).

Transmission mode: If the PEN bit is set in UART_CCR, then the MSB bit of the data written in the data register is transmitted but is changed by the parity bit (even number of ’1s’ if even parity is selected or an odd number of ’1s’ if odd parity is selected). If the parity check fails, the RXPERR_INTF flag is set in the UART_ISR register and an interrupt is generated if RXPERREN is preset.

20.3.7 Hardware flow control

It is possible to control the serial data flow between two devices by using the nCTS input and the nRTS output. The following figure shows how to connect two devices in this mode.

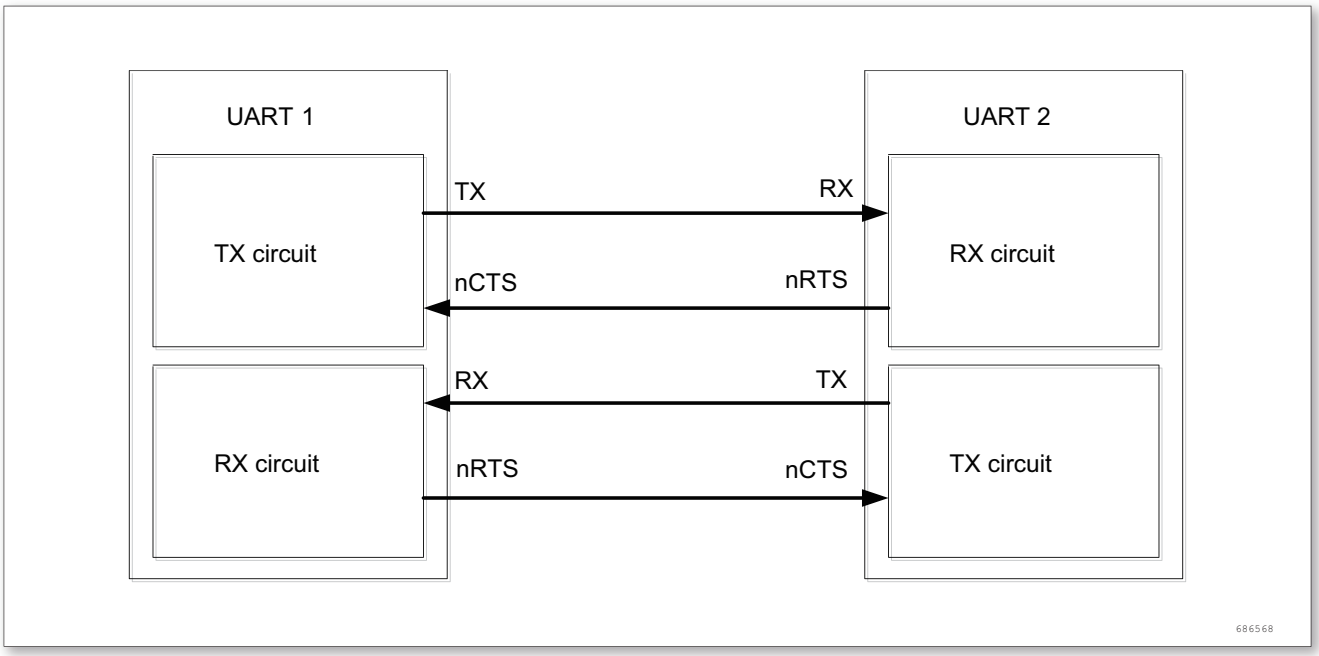

Figure 230. Hardware Flow Control Between Two UARTs

RTS and CTS flow control can be enabled by setting the AUTOFLOWEN bit in the UART_GCR.

RTS flow control

If the RTS flow control is enabled, then nRTS is active (tied low) as long as the UART receiver is ready to receive new data. When the receive register receives data, nRTS is released, indicating that the transmission is expected to stop at the end of the current frame. The following figure shows an example of communication with RTS flow control enabled.

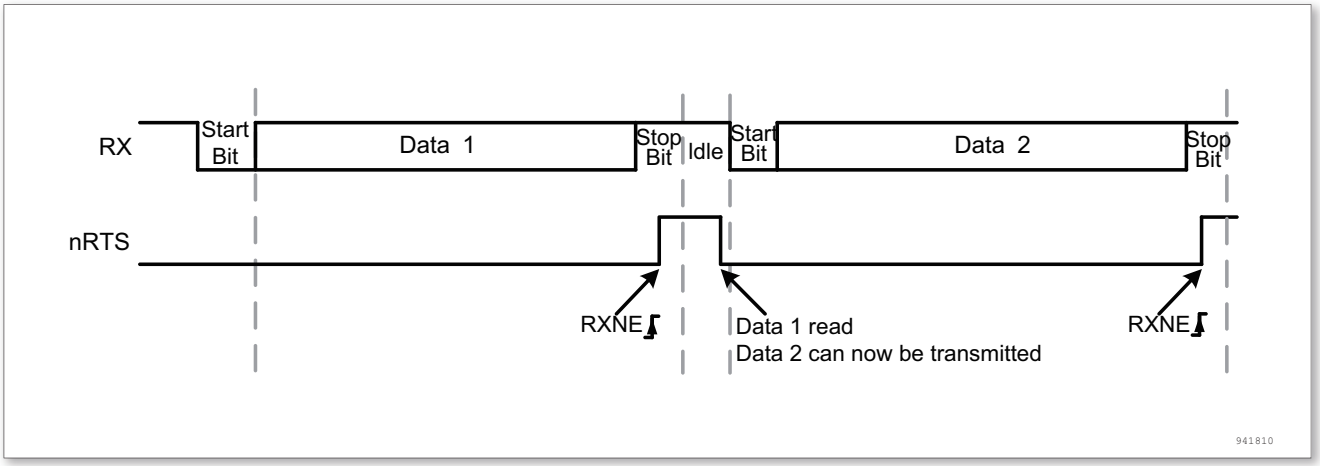

Figure 231. RTS Flow Control

CTS flow control

If the CTS flow control is enabled, then the transmitter checks the nCTS input before transmitting the next frame. If nCTS is active (tied low), then the next data is transmitted (assuming that a data is to be transmitted, in other words), else the transmission does not occur. When nCTS is inactive during a transmission, the current transmission is completed before the transmitter stops. The figure below shows an example of communication with

CTS flow control enabled.

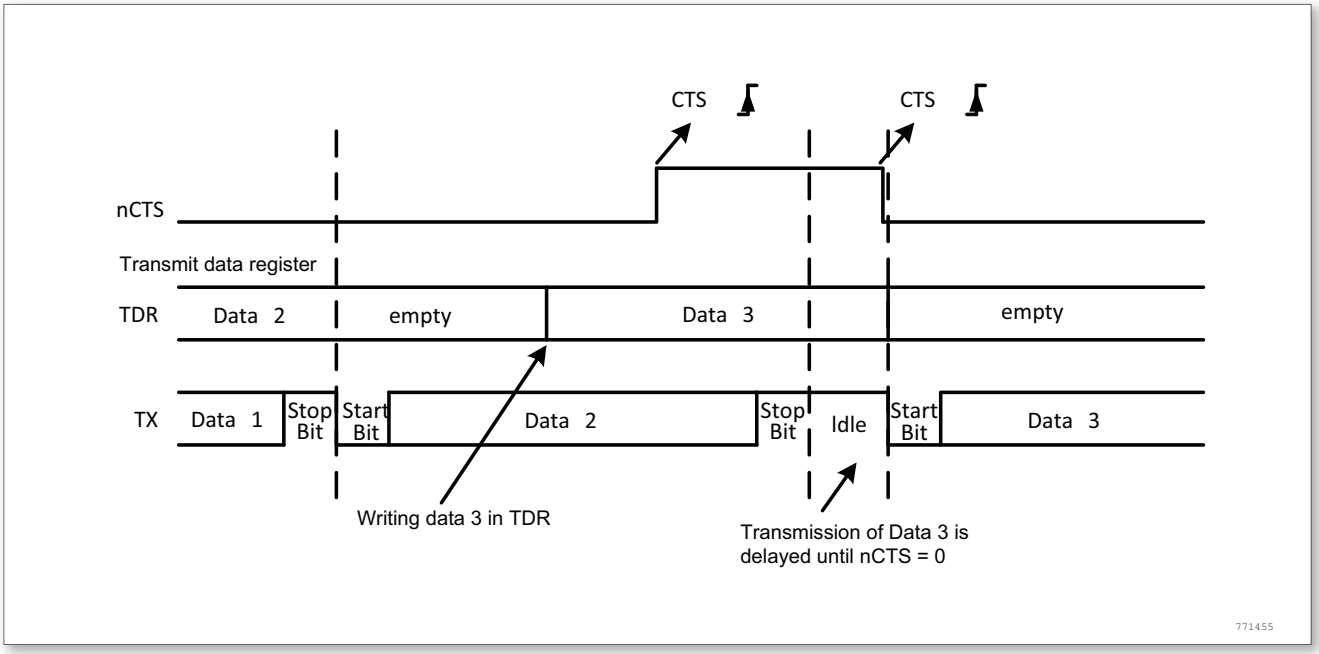

Figure 232. CTS Flow Control

20.3.8 Communication using DMA

The UART is capable of communicating using the DMA.

Transmission using DMA

During transmission using DMA, first configure the address of the UART_TDR register as the destination address of the DMA transfer in the DMA control register, configure the memory address as the source address of the DMA transfer, and configure the data volume. Then, enable DMA mode by setting the DMAMODE bit in the UART_GCR register. When the TXEN bit is set to ’1’, the DMA transfers data from the specified SRAM zone to the UART_TDR register.

Reception using DMA

During reception using DMA, first configure the address of the UART_RDR register as the source address of the DMA transfer in the DMA control register, configure the memory address as the destination address of the DMA transfer, and configure the data volume. Then, enable DMA mode by setting the DMAMODE bit in the UART_GCR register. When the RXEN bit is enabled, the DMA transfers data from the specified SRAM zone to the UART_RDR register.

20.4 UART interrupt requests

Table 64. UART interrupt requests

Interrupt event	Interrupt status	Enable bit
Transmit buffer null	TX_INTF	TXIEN
Valid data received	RX_INTF	RXIEN

Interrupt event	Interrupt status	Enable bit
Receive overrun error	RXOERR_INTF	RXOERREN
Parity error	RXPERR_INTF	RXPERREN
Frame error	RXFERR_INTF	RXFERREN
Break frame	RXBRK_INTF	RXBRKEN

These events generate an interrupt if the corresponding Enable Control Bit is set.

20.5 UART registers

21 Controller area network(CAN)

Controller area network(CAN)

21.1 CAN introduction

The CAN is designed to manage a high number of incoming messages efficiently with a minimum CPU load. It also meets the priority requirements for transmitting messages (priority characteristics configured by software).

For safety-critical applications, the CAN controller provides all hardware functions for supporting the Time Triggered Communication Mode.

21.2 CAN main features

- Supports CAN protocol version 2.0 A, and 2.0 B
- Extended receive buffer (64-byte, first-in and first-out (FIFO))
- Support both 11-digit and 29-digit identifiers
- Bit rate up to 1 Mbits/s
- PeliCAN mode extension
  - Error counter for read/write access
  - Programmable error warning limit
  - Last error code register
  - Interrupt for each CAN bus error
  - Arbitration lost interrupt controlled by specific control bits
  - Single transmission (no retransmission)
  - Listen-only mode (no confirmation and no activity error flag)
  - Software bit rate detection
  - Acceptance filter extension (4-byte code and 4-byte mask)
  - Own information reception (self-receive request)

21.3 CAN general description

In todayAs CAN applications, the number of nodes in a network is increasing and often several CANs are linked together via gateways. Typically the number of messages in the system (and thus to be handled by each node) has significantly increased. In addition to the application messages, Network Management and Diagnostic messages have been introduced.

An enhanced filtering mechanism is required to handle each type of message.

Furthermore, application tasks require more CPU time, therefore real-time constraints caused by message reception have to be reduced.

A receive FIFO scheme allows the CPU to be dedicated to application tasks for a long time period without losing messages.

The standard HLP (Higher Layer Protocol) based on standard CAN drivers requires an efficient interface to the CAN controller.

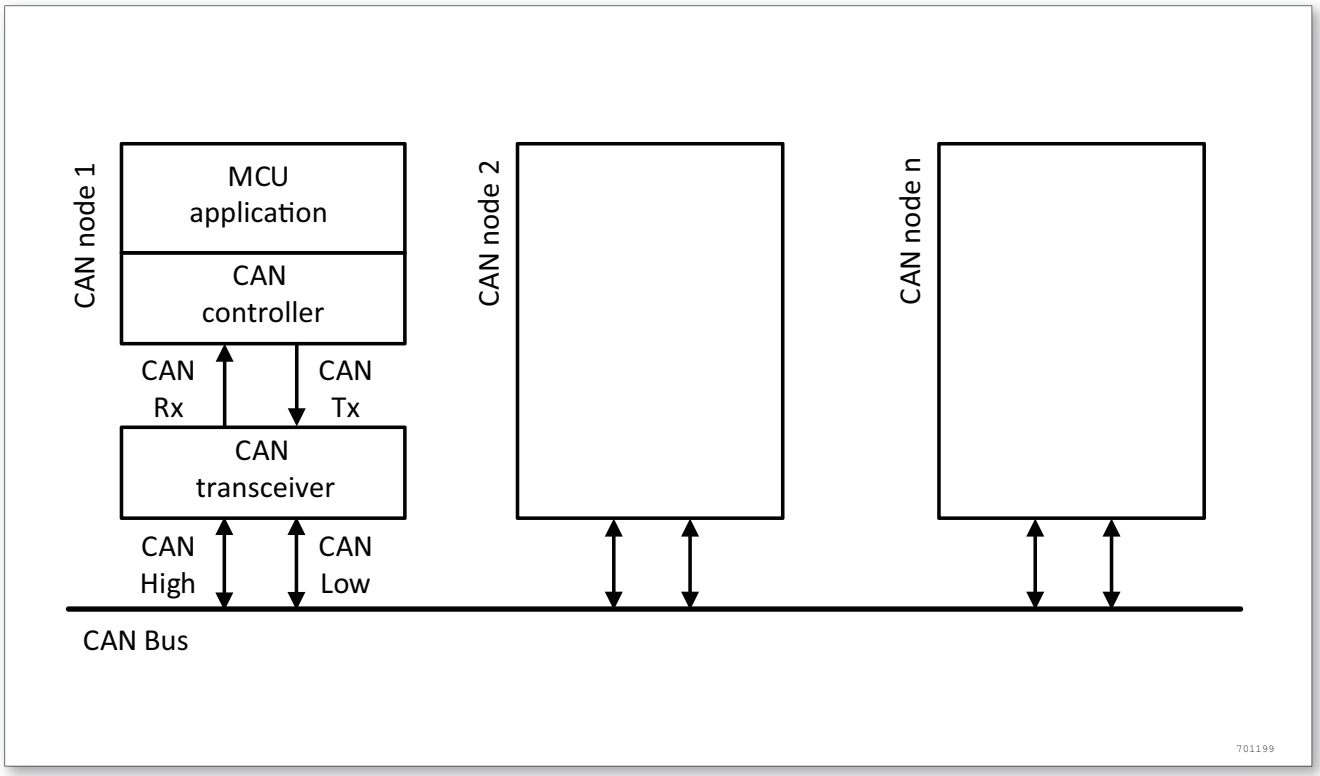

Figure 233. CAN Network Topology

21.3.1 CAN 2.0B active core

The CAN module handles the transmission and the reception of CAN messages fully autonomously, fully supporting standard identifiers (11-bit) and extended identifiers.

21.3.2 CAN block diagram

The block diagram of CAN is as follows:

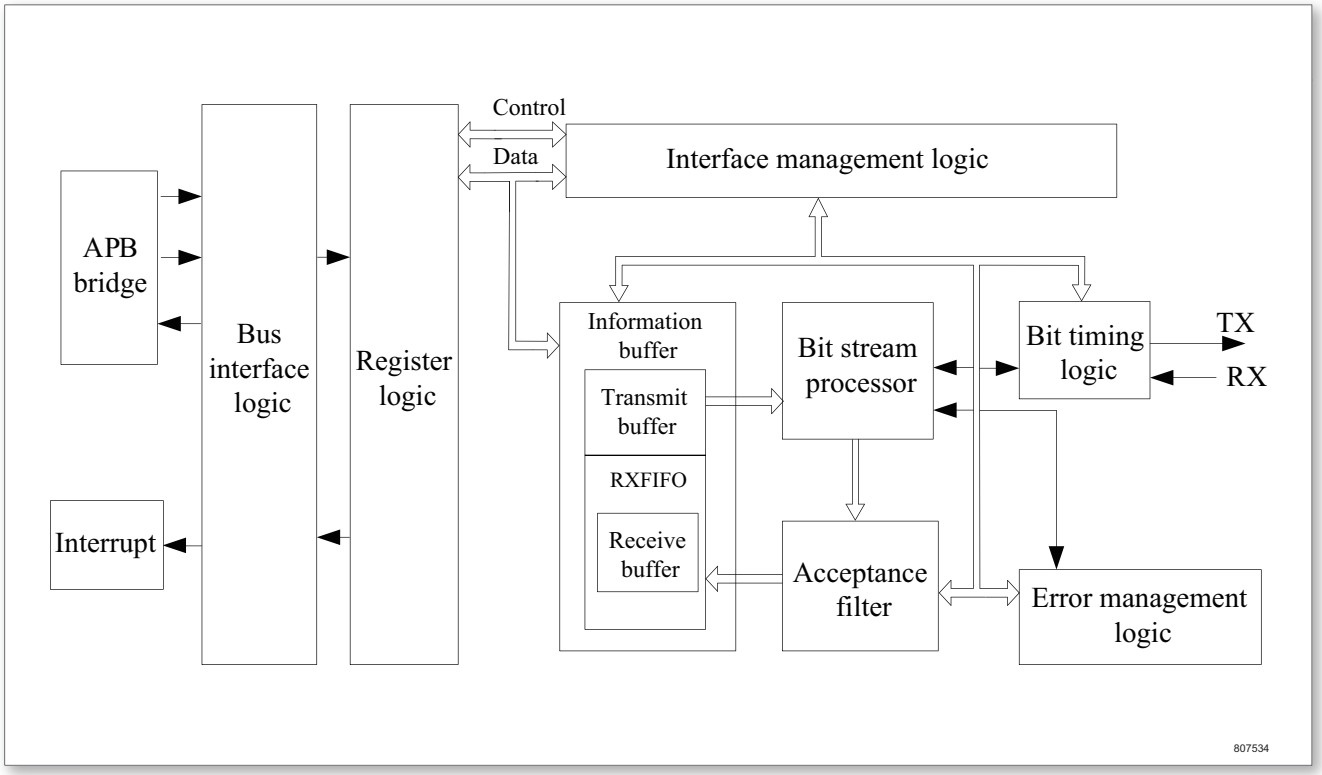

Figure 234. CAN Block Diagram

21.3.3 Interface management logic (IML)

The interface management logic interprets commands from the CPU and controls the addressing of the CAN registers, to provide interrupt information and status information to the master controller.

21.3.4 Transmit buffer (TXB)

The transmit buffer is the interface between the CPU and the BSP (bitstream processor), enabling storing the complete information sent to the CAN network. The buffer is 13 bytes long, written by the CPU and read by the BSP.

21.3.5 Receive buffer (RXB, RXFIFO)

The receive buffer is an interface between the acceptance filter and the CPU, enabling storing the information received from CAN bus and receive buffer (RXB, 13 bytes) as a window for the receive FIFO (RXFIFO, 64 bytes long). Additionally, the buffer can be accessed by the CPU.

With the support of this FIFO, the CPU enables receiving other information while processing information.

21.3.6 Acceptance filter (ACF)

The acceptance filter compares the data therein with the content of the received identifier, to determine whether to receive the information. In a pure reception test, all information is stored in the RXFIFO.

21.3.7 Bitstream processor (BSP)

The bitstream processor is a program device that controls the data flow between the transmit buffer, RXFIFO, and the CAN bus. It also performs error detection, arbitration, padding, and error handling on the CAN bus.

21.3.8 Bit timing logic (BTL)

The bit timing logic monitors the CAN bus of the serial port and handles the bit timing associated with the bus. It synchronizes the CAN bus bit stream (hard sync) during the bus transfer with the information preceded by 'weakness-dominant', and synchronizes the next transfer (soft sync) again when receiving the message. The BTL also provides a programmable time period, to compensate for propagation delay time, phase transitions, and defining sample points and number of samples per bit time.

21.3.9 Error management logic (EML)

EML is used for error control of the transport layer module, receiving an error report from the BSP, and informing the BSP and IML of the error statistics.

21.4 CAN operating mode

CAN has two main operating modes:

- BasicCAN mode
- PeliCAN mode

The default mode, during system reset, is BasicCAN mode.

The PeliCAN mode is a new operating mode, processing all frame types regulated in CAN 2.0B specifications. Moreover, it also supports some enhancements that make it available in a wider field.

The CAN mode is defined in the CAN_CDR.7 register. If CDR.7 is 0, the CAN controller operates in BasicCAN mode. Otherwise, it operates in PeliCAN mode.

21.4.1 Difference between Basic CAN and Peli CAN modes

In Peli CAN mode, the CAN controller has a recombination register with many functions. The Peli CAN mode supports all functions specified by the CAN 2.0B protocol (29-byte identifier). The following are the main new features of the PeliCAN mode:

- Reception and transmission of standard and extended frames
- Receive FIFO (64 bytes)
- Single- / dual- acceptance filters (including mask and code registers) in both standard and extended formats
- Error counter for read/write access
- Programmable error limit alarm
- Last error register
- Error interrupt for each CAN bus error
- Loss of arbitration and detailed bit position

- One-time transmission (no retransmission in case of error or arbitration lost)
- Listen-only mode (CAN bus monitoring, no response and no error flag)

21.5 CAN Functional description

21.5.1 Basic CAN mode

Reset mode

The reset mode is the initialization mode. The reset request bit (CAN_CR.0) is set to ’1’ (current) when the hardware is started or the bus status is set to ’1’ (bus-off). If these bits are accessed by software, their values will change and will affect the next rising edge of the internal clock. The read reset request bit of the internal frequency-division clock synchronization reflects the synchronization status when the reset request bit changes. The reset mode is mainly used for CAN communication parameter configuration, and the core has different access rights to the CAN register in different operating modes.

After the reset request bit is set to ’0’, the CAN controller will wait:

a) A bus idle signal (11 weak bits) if the previous reset request is a hardware reset or an initial CPU reset.

b) 128 buses are idle if the previous reset request is caused by the CAN controller initializing the bus before re-entering the bus-on mode; it must be noted that the values of some registers will be changed if the reset request bit is set.

Operating mode

After the reset mode, the software shall set the hardware into normal mode, to receive and send messages normally. In the reset mode, when a falling edge of ’1 - 0’ is transmitted to the reset bit, the CAN controller returns to the operating mode, to transmit and receive the message.

Note: ’(FFH)’ represents read data is all 1, ’—’ represents no write operation permission, and the rest represents ’permissible’.The ’clock divider’ with offset address 0x7C is used to select BasicCAN and PeliCAN.

21.5.2 Peli CAN mode

Reset mode

The reset mode is the initialization mode. The reset mode bit is set to ’1’ (current) when the hardware reset or bus status bit is ’1’ (bus-off). If this bit is accessed by software, the value will change and the rising edge of the next internal clock (frequency is 1/2 of the external oscillator) is active. The change of the reset request bit is synchronized with the internal frequency-division clock. The read reset request bit can reflect this synchronization state. After the reset mode bit is ’0’, the CAN controller will wait:

1. A bus idle signal (11 hidden (weak) bits) if the previous reset request is a hardware reset or an initial CPU reset.
2. 128 buses are idle if the previous reset request is caused by the CAN controller initializing before re-entering the bus-on mode.

Operating mode

After the reset mode, the software shall set the hardware into normal mode, to receive and send messages normally. In the reset mode, when a falling edge of '1 - 0' is detected on the RM bit of CAN_MOD register, the CAN controller returns to the operating mode, to transmit and receive the message.

Self-test mode

This mode is mainly used for testing. Set the self-test mode bit (CAN_MOD.2) to 1, to enter the self-test mode. In this mode, all nodes can be detected, and no self-receive command is used for the active node; even if there is no response, the CAN controller will send message successfully.

Listen-only mode

This is mainly used for testing. Set the Listen-only mode bit (CAN_MOD.1) to 1, to enable the Listen-only mode. In this operating mode, the CAN controller is in a false negative state, making information transfer impossible. The Listen-only mode is available for software-driven bit rate detection, and other functions can be used as they would in normal operating mode.

In this mode, the CAN controller is unable to write a dominant bit on the CAN bus. The activation error flag or the overload flag cannot be written, and the response signal will not be sent after successful reception.

Note: You must enter the reset mode before enabling the Listen-only mode.

21.5.3 Transmission handling

According to the CAN protocol specification, the message is transmitted independently by the CAN controller. The microcontroller is used to set the identifier, the data length and the data to be transmitted. Then, the 'Send Request' bit in the command register is set to '1' for RTS (request to send). The transmit buffer is write-locked when the CAN controller is transmitting a message. Therefore, before preventing a new message from being sent to the transmit buffer, the microcontroller must check the status register's 'Transmit Buffer Status' flag (TBS).

After the command bits CMR.0 and CMR.1 are set, a message transmission will occur immediately and no retransmission will appear in case of transmission error or arbitration lost (single transmission). The retransmission will be performed if only the command bit CMR.0 is set and data is failed to be sent. In the self-test mode, a self-receiving message will be generated immediately once the command bits CMR.4 and CMR.1 are set.

Abort

A transmission request of message can be aborted by setting the corresponding bit in the command register, namely, AT bit in CAN_CMR register is set to ’1’.

If CPU requires the pending of current transmission request, for example, a more urgent message needs to be sent first and the current transfer shall not stopped. To know if the source information is successfully sent, you can view it by sending the completion status bit. However, this shall be done after the status bit of transmit buffer is set to ’1’ or a transmit interrupt is generated.

It should be noted that a transmission interrupt occurs even if the information is aborted since the status bit of transmission buffer becomes ’released’.

If the transmission request in the previous instruction is set to ’1’, it cannot be disabled by setting the transmission request bit to ’0’, but shall be canceled by setting the abort transmission bit to ’0’.

21.5.4 Reception handling

The received message is processed independently by the CAN controller, and is sent to the receive buffer. The message that can be sent to the microcontroller is marked by the receive buffer status flag ’RBS’ in the status register and the receive interrupt flag ’RI’.

Query control reception

The microcontroller reads the status register of the CAN controller and checks the receive buffer status (RBS), to check if a message has been received.

When the RBS bit read is 1, it indicates that one or more messages have been received. The microcontroller retrieves the message from the CAN, and then sets the response flag ’RRB’ of the command register, to send a releasing receive buffer command.

Interrupt control reception

The interrupt enable flag is set in the CAN controller register (for BasicCAN mode) or in the interrupt enable register (for PeliCAN mode). If the CAN controller has received a message and the message has been processed by the acceptance filter and sent to the receive FIFO, a receive interrupt will be generated. Then, the interrupt service routine is enabled, the message is fetched by the microcontroller, and the response flag bit ’RRB’ of the command register is set, to send a releasing receive buffer command.

Overrun

An overrun occurs when the receive FIFO is full but another message is received, and the data overload status bit in the status register is set (if enabled), to inform the microcontroller of the data overrrun. The status can be cleared by setting CMR.3 bit to ’1’.

Valid message

A received message is considered as valid when it has been received correctly according to the CAN protocol (no error until the last but one bit of the EOF field) and it passed through the identifier filtering successfully.

The RRB bit in the CAN_CMR register is used to clear the data overrun indicated by the

data overrrun status bit.

21.5.5 Identifier filtering

In the CAN protocol, the identifier of a message is not associated with the address of a node but related to the content of the message. Consequently, a transmitter broadcasts its message to all receivers. During message reception, a receiver node decides - depending on the identifier value - whether the software needs the message or not. If the message is needed, it is copied into the BUFFER. If not, the message must be discarded without intervention by the software.

The stand-alone CAN controller is equipped with a multifunctional acceptance filter that enables automatic checking of identifiers and data bytes. With these efficient filtering methods, it is possible to prevent invalid messages or message groups in a node from being stored in the receive buffer, thus reducing the processing load on the microcontroller.

The filter is controlled by the acceptance code register and the mask register according to a given algorithm. The received data is compared bit by bit with the values in the acceptance code register. The receive mask register defines the location associated with the comparison (0 = correlated, 1 = uncorrelated). The message will only be received if the corresponding bit of the received message is the same as that in the acceptance code register.

Acceptance filter in BasicCAN mode

The filter is controlled by two registers, the acceptance code register (ACR) and the acceptance mask register (AMR). The upper 8 bits of the CAN message identifier are compared to the values in these registers, to define the identifiers of several groups to be received by any node.

Example: acceptance code register (ACR) includes:

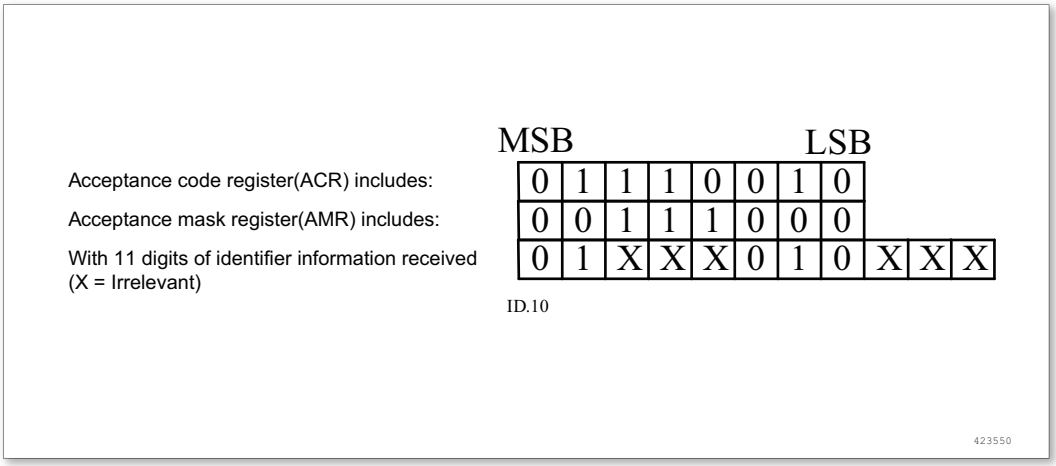

Figure 235. Example of CAN Identifier Reception

In position of ’1’ in the acceptance mask register, the corresponding bit of the identifier can be any value. This is the same for the three lowest bits. Therefore, in this example, you can receive 64 different identifiers; the other bits of the identifier must be equal to the value of the corresponding bit in the acceptance code register.

Acceptance filter in PeliCAN mode

With the help of the acceptance filter, the CAN controller allows the received information to be stored in the RXFIFO only when the identification bits in the received message and the predefined values of the acceptance filter are equal.

In PeliCAN mode, the acceptance filter is defined by the acceptance code register (ACRn) and the acceptance mask register (AMRn), and the bit pattern of the information to be received is defined in the acceptance code register. The corresponding acceptance mask register allows certain bits to be defined as 'no effect' (i.e. any value).

There are two different filtering modes that can be selected in bit 3 of the mode register:

- Single filter mode$^{(1)}$
- Dual-filter mode$^{(0)}$

Single filter configuration

This filter configuration defines a long filter (4 bytes). The correspondence between the bits of the filter byte and the information byte depends on the current received frame format.

Standard frame: If the information in the standard frame format is received, only the first two data bytes are used during the acceptance filtering, to store the complete identifier including the RTR bit. In case of no data byte due to the RTR bit set, or no or only one data byte due to corresponding data length code configured, the message will be also received. For a successfully received message, the receipt signal must be sent after comparison of individul bits.

Note: The lower four bits of ACR1 and AMR1 are not used. For compatibility with future products, these bits can be defined as 'no effect' by setting AMR1.3, AMR1.2, AMR1.1 and AMR1.0 to 1.

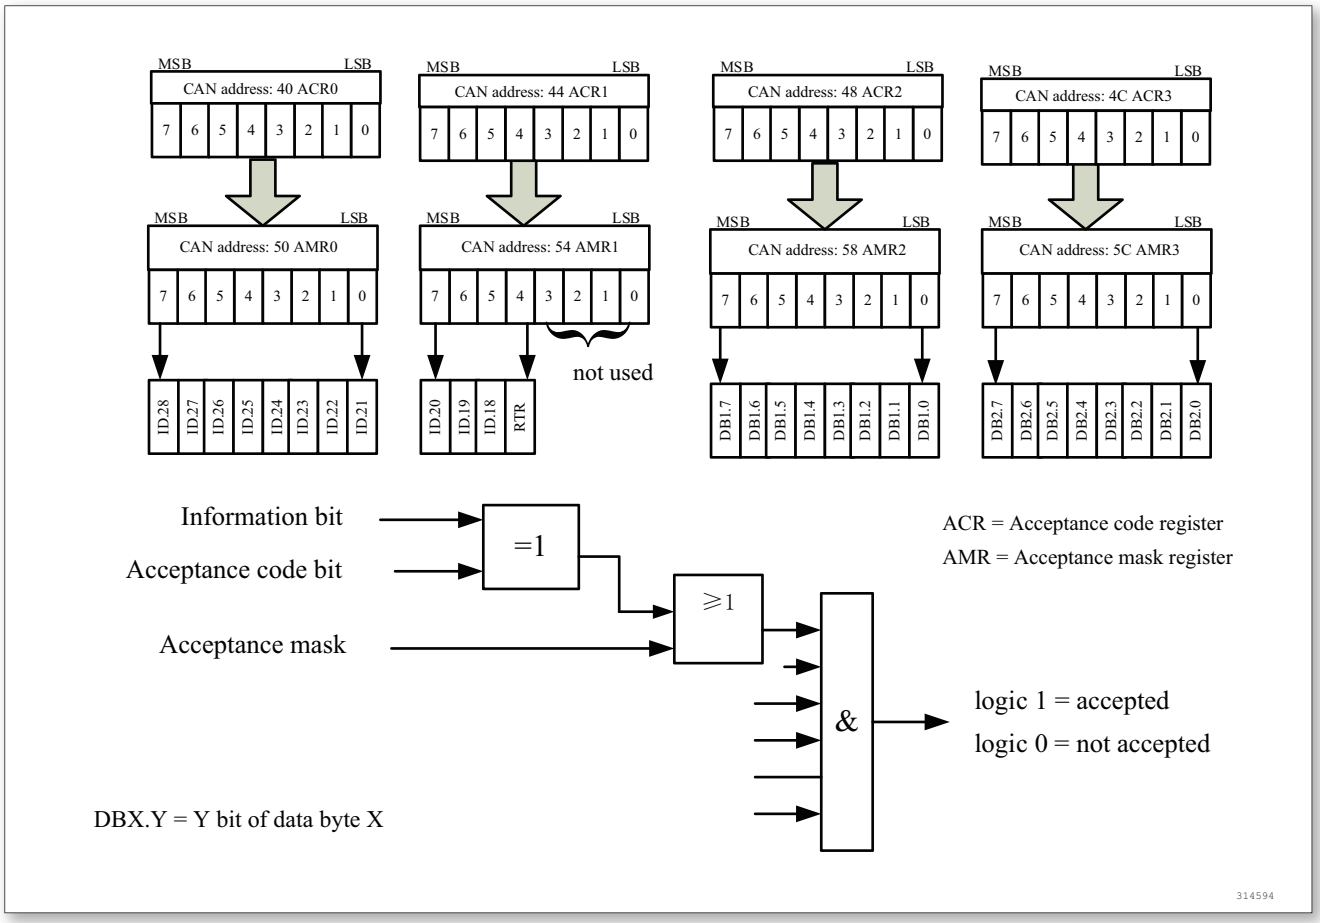

Figure 236. Single Filter Configuration When Receiving Information of Standard Structure

Extended frame: If the received message is in extended frame format, all identifiers including the RTR bit will be used for receive filtering.

In order to successfully receive information, each bit must be compared.

Note: The lowest two bits of AMR3 and ACR3 are not used. These bits shall be defined as 'no effect' by setting AMR3.1 and AMR3.0.

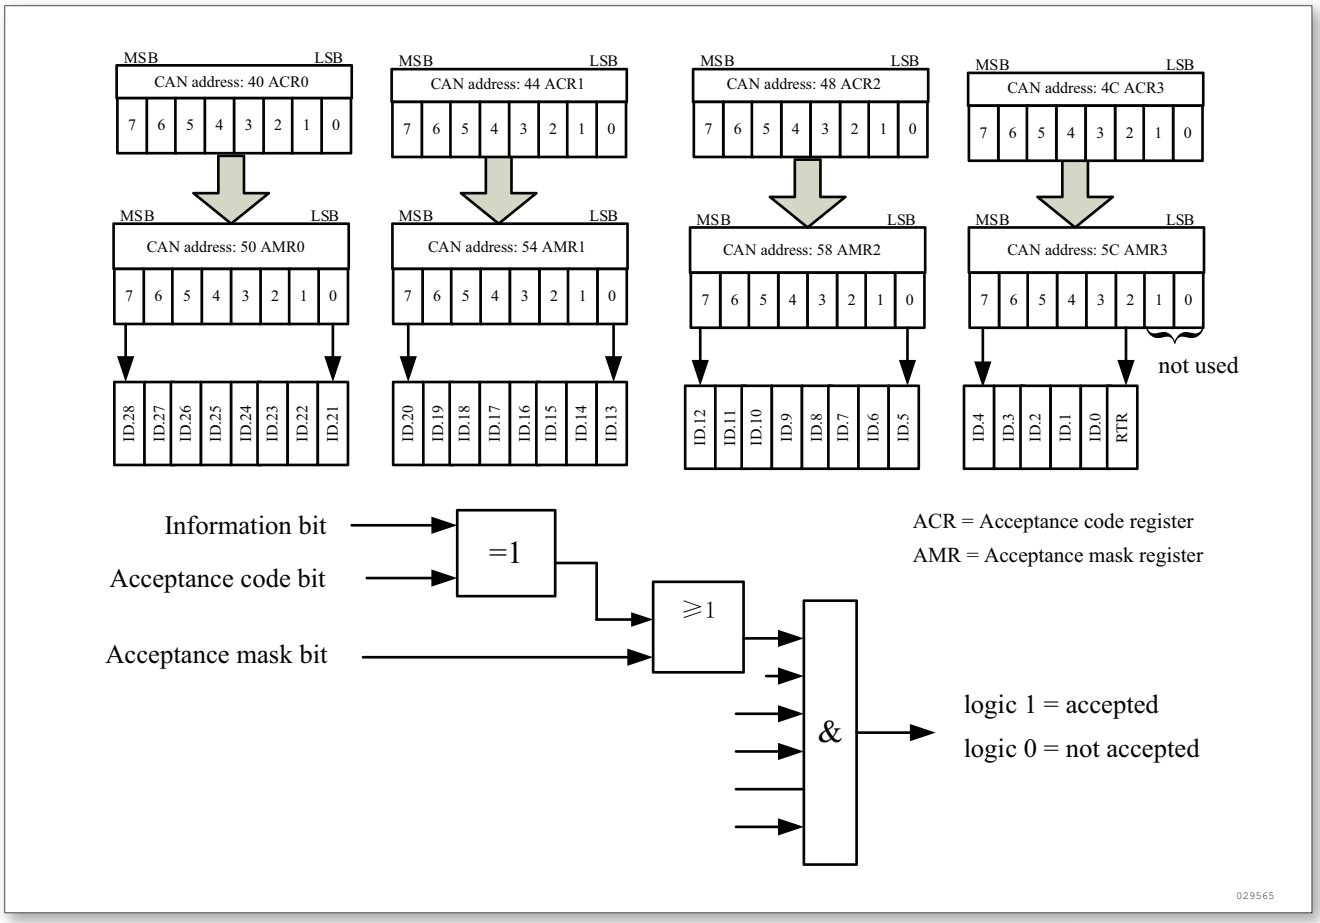

Figure 237. Single Filter Configuration for Receiving Extended Frame Information

Dual-filter configuration

This configuration can define two short filters. A received message is compared to that of two filters, to determine if it is stored in the receive buffer. The received message is valid only when at least one filter sends a received signal. The correspondence between the bits of the filter byte and the information byte depends on the currently received frame format.

Standard frame: If the standard frame information is received, the two filters defined are different. For the first filter, the entire standard identifier of the RTR bit and the first data byte of the message are compared; for the second filter, only the entire standard identifier including the RTR bit is compared.

In order to receive information successfully, at least one filter shall indicate the reception when all individual bits are compared. If the RTR bit is set or data length code is 0, no data byte exists. In any case, as long as the part from the first bit to the RTR bit indicates the reception, the information can be processed by Filter 1.

If no data byte filtering is requested from the filter, the lower four bits of AMR1 and AMR3 must be set to ’1’ (no effect). Both filters operate when the entire standard identifier including the RTR bit is used.

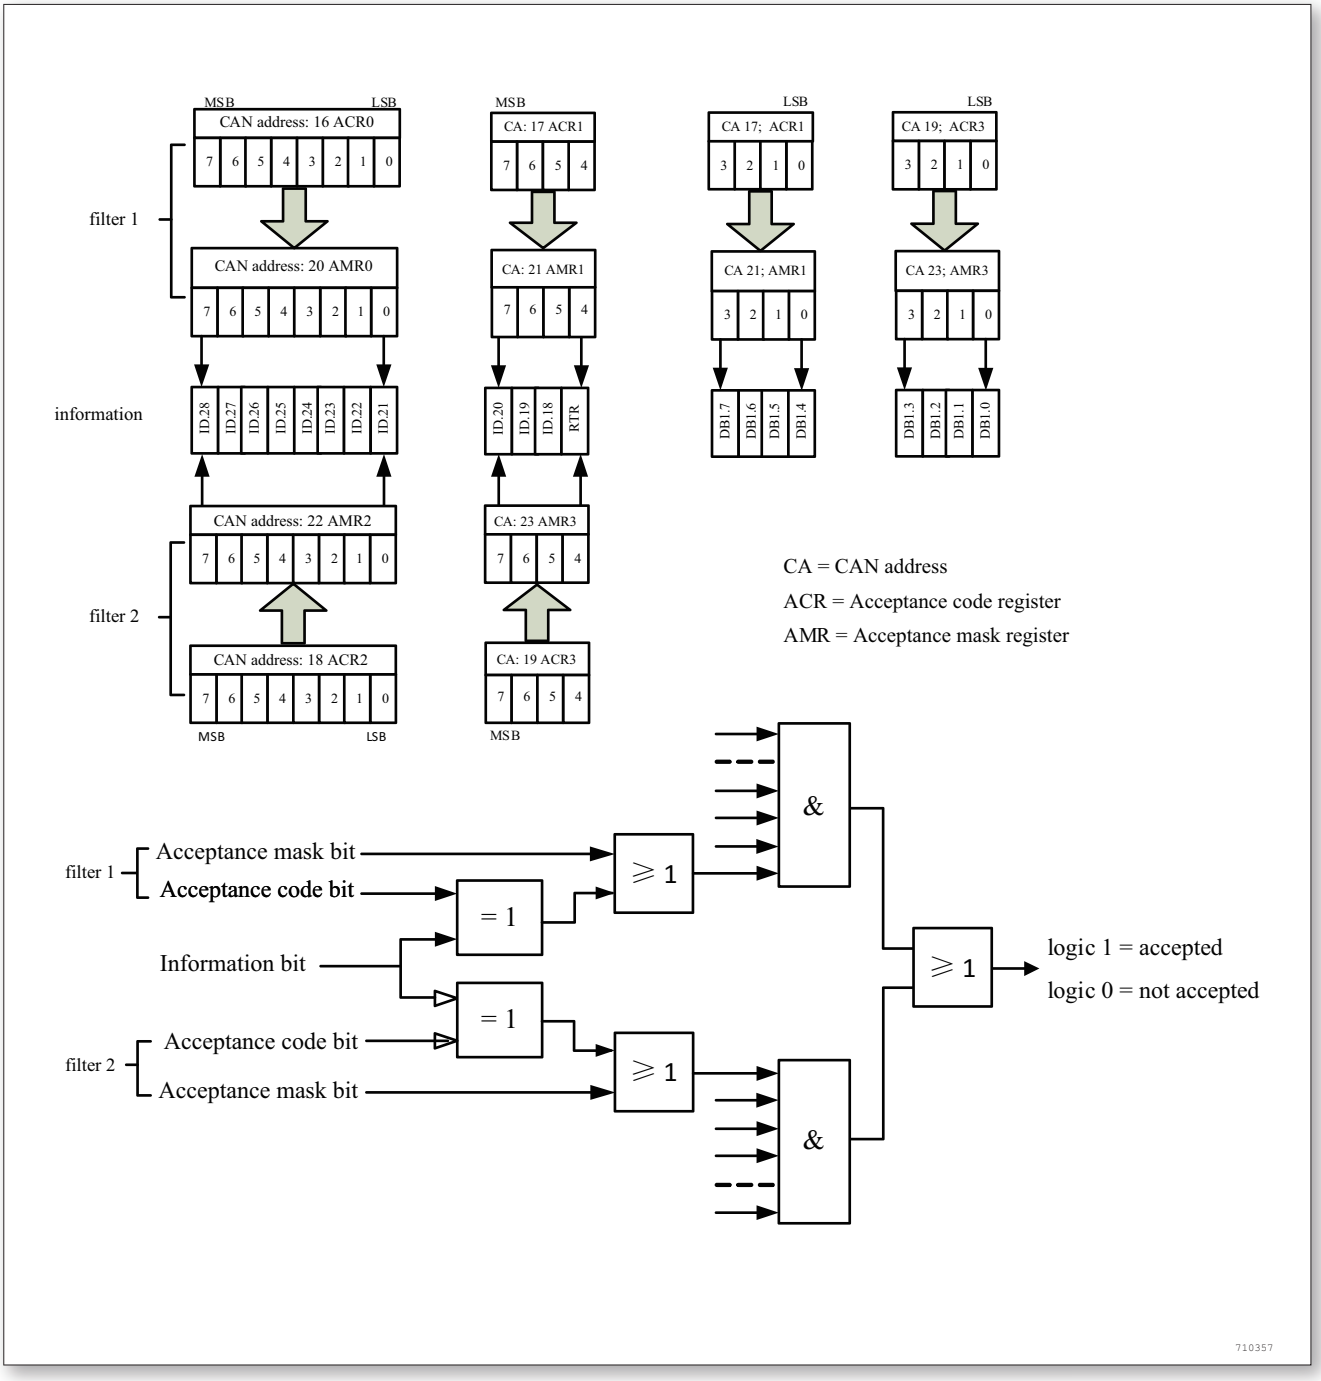

Figure 238. Dual-filter Configuration When Receiving Information of Standard Structure

Extended frame: If the extended frame information is received, the two defined filters are identical. For both filters, only the first two bytes of the extended identifier are compared.

In order to receive the information successfully, at least one filter indicates reception during the comparison of all the individual bits.

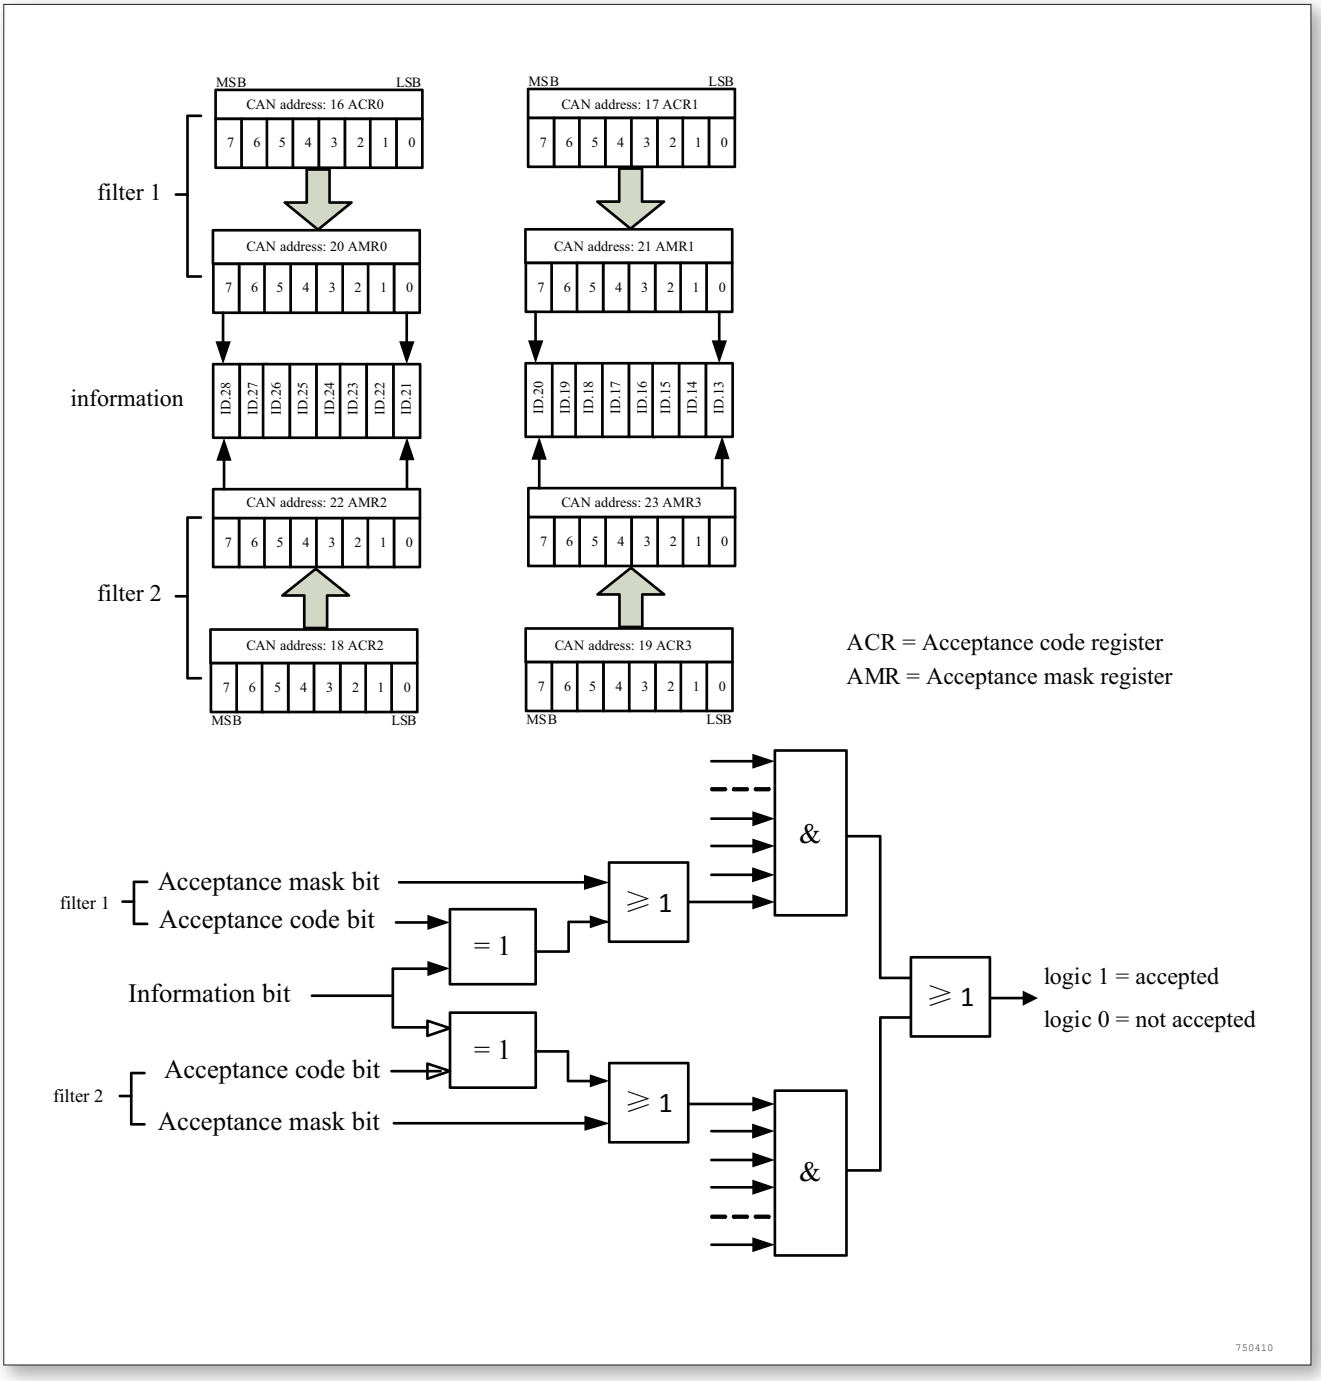

Figure 239. Dual-filter Configuration for Receiving Extended Frame Information

Example 1: Assume that the following 1 standard frame message will be filtered in Peli-CAN mode, which can be achieved with a long filter (single filter mode).

The acceptance code register (ACRn) and the acceptance mask register (AMRn) include:

n	0	1(upper four bits)	2	3
ACRn	01XX X010	XXXX	XXXX XXXX	XXXX XXXX
AMRn	0011 1000	1111	1111 1111	1111 1111

n	0	1(upper four bits)	2	3
Received message(ID28 ~ ID.18, RTR)	01xx x010 xxxx			

'X' = uncorrelated, 'x' = any value, only the upper four bits of ACR1 and AMR1 are used.

Example 2: Assume that the following two messages with standard frame identifiers are received without further decoding. Data and remote frames must be received correctly and the data byte requires no acceptance filtering.

Message 1: (ID.28)1011 1100 101(ID.18)

Message 2: (ID.28)1111 0100 101(ID.18)

With the single filter mode, you can receive four messages instead of the two required:

n	0	1(upper four bits)	2	3
ACRn	1X11 X100	101X	XXXX XXXX	XXXX XXXX
AMRn	0100 1000	0001	1111 1111	1111 1111
Received message(ID28 ~ ID.18, RTR)	1011 0100 101x 1111 0100 101x (Message 2) 1011 1100 101x (Message 1) 1111 1100 101x			

'X' = uncorrelated, 'x' = any value, only the upper four bits of ACR1 and AMR1 are used.

This result requires further decoding, to meet the requirements for receiving two messages.

Get the right results by using double filters.

	Filter 1			Filter 2	
n	0	1	3 lower four bits	2	3 upper four bits
ACRn	1011 1100	101X XXXX	... XXXX	1111 0100	101X ...
AMRn	0000 0000	0001 1111	... 1111	0000 0000	0001 ...
Received information(ID28 ~ ID.18, RTR)	1011 1100 101X(Message 1)			1111 0100 101X(Message 2)	

'X' = uncorrelated, 'x' = any value.

Message 1 is received by Filter 1 and message 2 received by Filter 2. If the message is received by at least one of the two filters, the message will be stored in the receive FIFO. This method satisfies this requirement.

Example 3: In this example, a long acceptance filter is used to filter message groups with extended identifiers.

n	0	1	2	3(upper six bits)
ACRn	1011 0100	1011 000X	1100 XXXX	0011 0XXX
AMRn	0000 0000	0001 0001	0000 1111	0000 0111
Received information(ID28 ~ ID.18, RTR)	1011 0100 101x 000x 1100 xxxx 0011 0x			

'X' = uncorrelated, 'x' = any value, only the upper six bits of ACR1 and AMR1 are used.

Example 4: The standard frame system is used to identify messages only with the 11-bit identifier and the first two data bytes. If the message exceeds 8 data bytes, the first two data bytes are defined as the message header and the segmented storage protocol uses such a protocol, such as DeviceNet. For this type of system, the CAN controller enables filtering two data bytes in single filter mode in addition to the 11-bit identifier and RTR bit, and enables filtering one data byte in dual filter mode (except for the 11-bit flag and RTR bits).

The following example shows the process of effectively filtering the message in such a system in the dual-filter mode:

	Filter 1			Filter 2	
n	0	1	3 lower four bits	2	3 upper four bits
ACRn	1110 1011	0010 1111	... 1001	1111 0100	XXX0 ...
AMRn	0000 0000	0000 0000	... 0000	0000 0000	1110 ...
Received information(ID28 ~ ID.18, RTR)	1110 1011 0010 + 1111 ... 1001 Identifier RTR + first data byte			1111 0100 Identifier	xxx0 RTR

('X' = uncorrelated, 'x' = any value)

- Filtered messages in Filter 1 include:
  - Identifier '11101011001'
  - RTR = '0', namely, the data frame
  - Data byte '11111001' (this means that, such as DeviceNet, all segments of a message are filtered)
- Filter 2 is used to filter a group of 8 messages, in which the message includes:
  - Identifier '11110100 000' to '11110100111'
  - RTR = '0', namely, the data frame

21.5.6 Message storage

The data to be sent on the CAN bus is loaded into the CAN controller's memory area, which is called the 'transmit buffer'; the data received from the CAN bus is also stored in the CAN controller's memory area, the 'receive buffer'. These buffers contains 2- , 3- or 5-byte identifiers and frame information (depending on mode and frame type), with the maximum capacity of 8 data bytes.

BasicCAN mode

The buffer up to 10 bytes contains:

- 2 identifier bytes
- 8 data bytes

Table 68. RX and TX Buffers in BasicCAN Mode

Relative CAN offset		Register		Composition and notes
TX (hexadecimal)	RX (hexadecimal)	TX	RX	
28	50	CAN_TXIDR1	CAN_RXIDR1	8-bit identifier
2C	54	CAN_TXIDR2	CAN_RXIDR2	3-bit identifier and 1-bit remote transmission request bit (4 bits), According to the length code, it represents the number of data bytes
30	58	CAN_TXDR1	CAN_RXDR1	Represented by the data length code (up to 8 data bytes)
34	5C	CAN_TXDR2	CAN_RXDR2	
38	60	CAN_TXDR3	CAN_RXDR3	
3C	64	CAN_TXDR4	CAN_RXDR4	Represented by the data length code (up to 8 data bytes)
40	68	CAN_TXDR5	CAN_RXDR5	
44	6C	CAN_TXDR6	CAN_RXDR6	
48	70	CAN_TXDR7	CAN_RXDR7	
4C	74	CAN_TXDR8	CAN_RXDR8	

PeliCAN mode

The 13-byte buffer contains:

- 1-byte frame information
- 2 or 4 identifier bytes (standard or extended frame)
- Up to 8 data bytes

Transmit buffer

The complete list of transmit buffers is as shown below. Note to distinguish between standard frame format (SFF) and extended frame format (EFF) configurations. The transmit buffer allows to define the received message up to 8 data bytes.

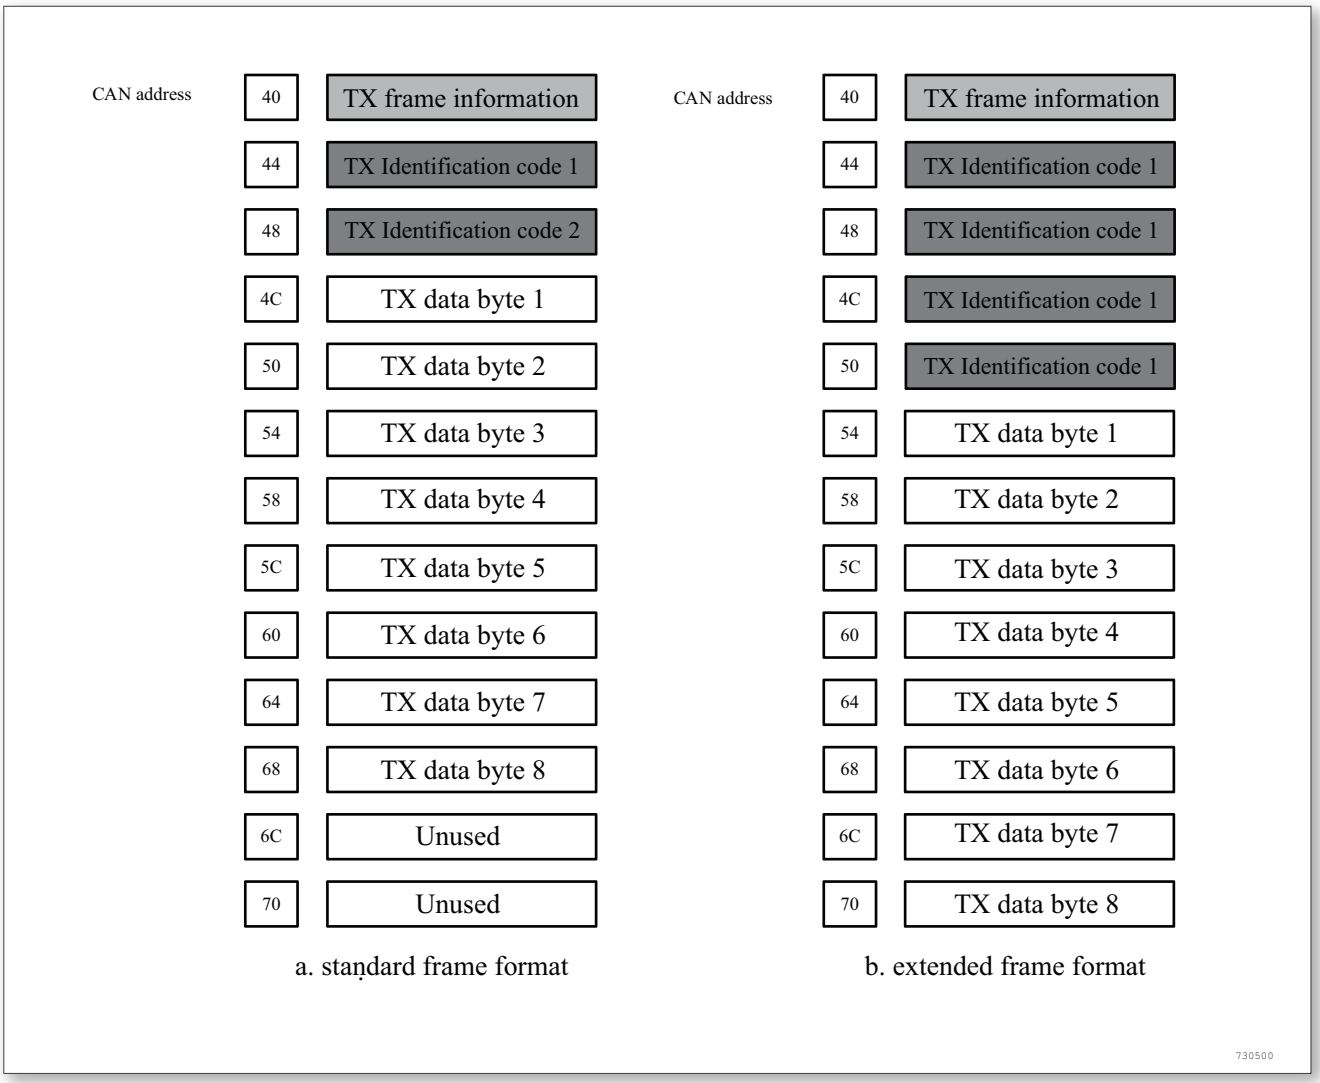

Figure 240. List of Standard frame and Extended Frame Format Configured in Transmit Buffers

The FF bit in the frame information determines whether the CAN controller sends messages in the extended frame format or those in the standard frame format.

Receive buffer

The list of receive buffers is very similar to the transmit buffers. The receive buffer is the accessible part of the RXFIFO, occupying 40 ~ 70 of the CAN address. Each message is divided into a description area and a data area.

The received byte length code in the frame information byte represents the actual transmitted data length code, which may be greater than 8 (depending on the transmitter). In any case, the maximum received data byte is 8, and this should be considered when reading the information in the receive buffer.

As shown in the figure below, the RXFIFO has a space of 64 information bytes in total. The information that can be stored at a time depends on the length of the data. If there is not enough space in the RXFIFO to store new information, a data overrun will occurs in the CAN controller, at the moment, the message is valid and the receive test is required. In case of data overflow, information that has been written to the RXFIFO will be deleted, and

the conditionn can be reported to CPU through the status register and the data overrun interrupt (interrupt enable).

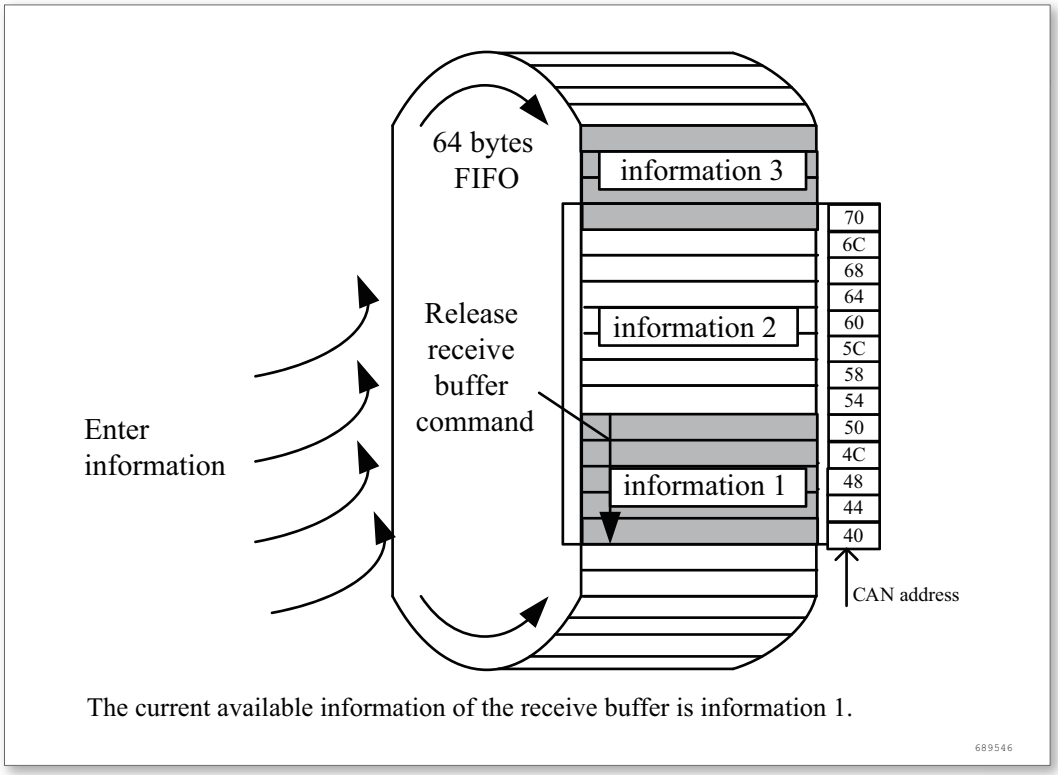

Figure 241. List of Standard frame and Extended Frame Format Configured in Transmit Buffers

21.5.7 Error management

Based on the value of the error counter, each CAN controller operates in one of three error states: Error Active, Error Pasitive, or Bus Offline. If the value of the error counter is between 0 ～127, the CAN controller is incorrectly activated. At this time, an Error Active flag (6 dominant bits) is generated. If the value of an error counter is between 128～255, the CAN controller is incorrectly recognized. At this time, an Error Pasitive flag (6 recessive bits) is generated before an error is detected. If the value of the transmit error counter is higher than 255, the bus is offline. In this state, the reset request is automatically set and the CAN controller has no effect on the bus. The bus offline status can only be exited through the microcontroller with the command 'reset request = 0'. This will activate the bus offline recovery timer and send 128 bus release signals to the error counter. After the counting, both error counters are 0 and the device is again in the Error Active state.

Error counter

As described above, the error state of the CAN is directly related to the value of the transmit error counter and the receive error counter.

In order to carefully study the error definition, the CAN controller supports the enhanced error analysis function, and provides a readable error counter. In addition, in reset mode, write access is allowed for both error counters.

Error interrupt

Three interrupt sources are used to send the error status to the microprocessor. Each interrupt can be separately enabled in the interrupt enable register.

- Bus error interrupt: an interrupt is generated when any error is detected on the CAN bus
- Error warning interrupt: If the error warning limit is exceeded, an error warning interrupt is enabled. Moreover, this interrupt is also generatged when the CAN controller enters the bus offline state and reenters the Error Active state. The error warning limit of the CAN controller is programmable in reset mode, and the default value after reset is 96.
- Error Pasitive interrupt: If the error status changes from Error Active to Error Pasitive or vice versa, an Error Pasitive interrupt will be generated.

Error code capture

The CAN controller can perform all the error definitions regulated in the CAN2.0B specifications. The entire process of error handling for each CAN controller is completely automatic. However, in order to provide the user with the details of an error, the CAN controller supports the error code capture function. Whenever a CAN bus error occurs, it forces a corresponding bus error interrupt. At the same time, the current bit is captured into the error code capture register; the captured data is saved in the register before being read by the main controller. Then, the capture mechanism is activated again; the register enables distinguishing between four types of errors: format errors, padding errors, bit errors, and other errors. As shown in the figure below, the register additionally indicates whether the error occurs during the reception or transmission of the message. The five bits in this register indicate the bit of the frame error in the CAN. Refer to the table and data table below for more information.

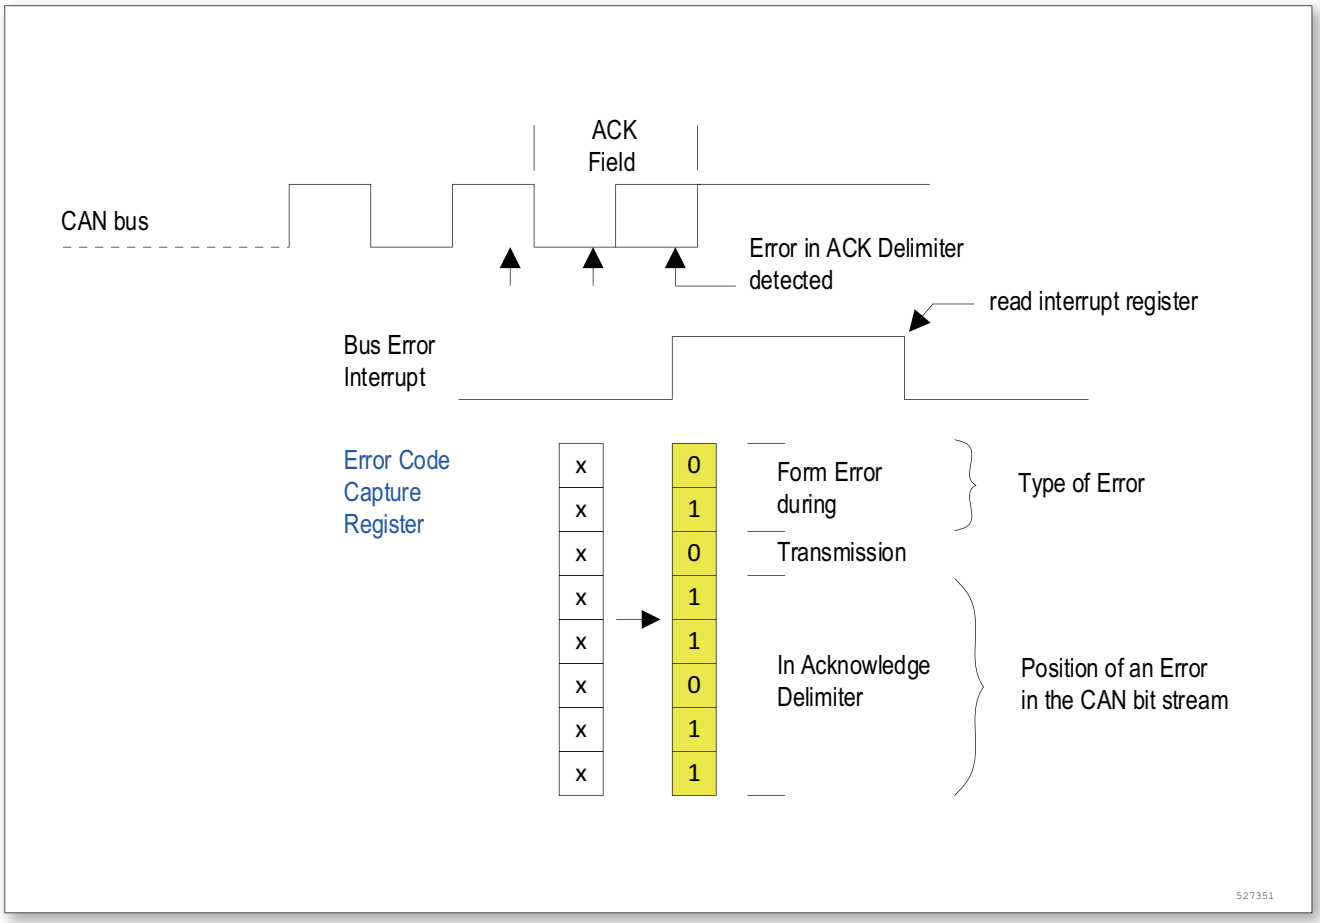

Figure 242. Example of Error Code Capture Function

The CAN specifications define that each bit on the CAN bus has only a special type of error. The following two figures show all the errors that may occur during CAN message transmission and reception. The left part includes the position and error type, which are captured by the error code capture register; the right part of each table is an error description that converts the error code into the upper layer, which can be directly interpreted from the contents of the register. By using these tables, you can get more information about the error counter changes and the error status of the transmit and receive pins. When using these tables, such as in the error analysis software, each error state can be analyzed in detail. Information about the type and location of CAN errors can be used for error statistics and system maintenance or for corrections in system optimization devices.

Table 69. Possible Errors During Reception

Error location in CAN bitstream	Error type	RX error count	Error code capture	Description
Identifier SRR、IDE and RTR bits Reserved bit Data length code Data field CRC sequence	Padding	+1	Receive 5 consecutive bits of the same level	–
CRC delimiter	Format Padding	+1 +1	RX = dominant, Receive 5 consecutive bits of the same level	Bit must be recessive
Acknowledge bit	Bit	+1	RX = dominant, or CRC error detected	Critical bus timing or bus length CRC sequence incorrect
Acknowledge delimiter	Format	+1	RX = dominant, or CRC error detected	Critical bus timing or bus length CRC sequence incorrect
End of frame	Format Others	+1 ±0	RX = the first six bits are dominant, RX = the last bit is dominant	– Reaction: An overload flag is issued, and the data may be repeated if it is resent by the transmitter
Interval	Others	±0	RX = dominant	Reaction: Receiver sends an overload flag
Activation error flag	Bit	+8	TX = dominant, but RX = recessive	Not allowed to write dominant bits
Allowable dominant bit	Others	+8	TX = dominant, but RX = recessive	Not allowed to write dominant bits
Error delimiter	Format Others	+8	TX = dominant, but RX = recessive	Not allowed to write dominant bits
Overload flag	Bit	+8	TX = dominant, but RX = recessive	Not allowed to write dominant bits

Table 70. Possible Errors During Reception

Error location in CAN bitstream	Error type	TX error count	Error code capture	Description
Start of frame	Bit	+8	TX = dominant, but RX = recessive	Not allowed to write dominant bits

Error location in CAN bitstream	Error type	TX error count	Error code capture	Description
Identifier	Bit padding	+ 8 ± 0	TX = dominant, but RX = recessive; TX = recessive, but RX = dominant	Not allowed to write dominant bits –
SRR bit	Bit padding	+ 8 ± 0	TX = dominant, but RX = recessive; TX = recessive, but RX = dominant	Not allowed to write dominant bits –
IDE and RTR bits	Bit padding	+ 8 ± 8	TX = dominant, but RX = recessive; TX = recessive, but RX = dominant	Not allowed to write dominant bits –
Reserved bit Data length code Data field CRC sequence	Bit	+8	TX = dominant, but RX = recessive	Not allowed to write dominant bits
CRC delimiter	Format	+8	RX = dominant	Bit must be recessive
Acknowledge slot	Others Others	+ 8 ± 0	RX = recessive (Error Active), RX = recessive (Error Pasitive)	No response No response; the node may be on the bus separately
Acknowledge delimiter	Format	+8	RX = dominant	Critical bus timing or bus length
End of frame	Formats Others	+8 +8	RX = the first six bits are dominant, RX = the last bit is dominant	– The frame has been received by some nodes, and resending may lead to repeated data in the receiver
Interval	Others	±0	RX = dominant	Overload flag from the 'old' CAN controller
Activation error flag Overload flag	Bit	+8	TX = dominant, but RX = recessive	Not allowed to write dominant bits
Allowable dominant bit	Format	+8	RX = more than 7 dominant bits preceded by activation error or overload flag	–

Error location in CAN bitstream	Error type	TX error count	Error code capture	Description
Error delimiter	Format Others	+8 ±0	RX = the first seven bits are dominant, RX = the last bit of the delimiter is a dominant bit	–
Passive Error flag	Others	+ 8	RX = dominant(Error Pasitive)	No response; the node is not on the bus separately

Offline recovery

If the value of the transmit error counter is higher than 255, the bus is offline, and the bus status bit is set to '1'. In this state, the reset request bit is automatically set and the CAN controller has no effect on the bus. In case of an error interrupt enabled, an error interrupt is generated. This state continues until the CPU clears the reset request bit. After that, the CAN controller will wait for the minimum time specified by the protocol (128 idle bus signals).

21.5.8 Bit-time characteristics

The bit timing logic monitors the serial CAN bus by sampling and performs sampling and adjustment of the sample point by synchronizing on the start-bit edge and resynchronizing on the following edges.

Its operation may be explained simply by splitting nominal bit time into three segments as follows:

- Synchronization segment ($t_{SYNCSEG}$): a bit change is expected to occur within this time segment. It has a fixed length of one time quantum (1 x t_{CAN}).
- Bit segment 1(t_{TSEG1}): It defines the location of the sample point. It includes the PROP_SEG and PHASE_SEG1 of the CAN standard. Its duration is programmable between 1 and 16 time quanta but may be automatically lengthened to compensate for positive phase drifts due to differences in the frequency of the various nodes of the network.
- Bit segment 2(t_{TESG2}):It defines the location of the transmit point. It represents the PHASE_SEG2 of the CAN standard. Its duration is programmable between 1 and 8 time quanta but may also be automatically shortened to compensate for negative phase drifts.

The period of t_{SCL}, the CAN system clock, is programmable and determines the corresponding bit timing.

The CAN system clock is calculated by the following equation: $t_{SCL} = 2 \times t_{CLK} \times (BRP + 1)$. Where, t_{CLK} = APB1 frequency period

Synchronization jump width (SJW) defines the upper limit of how many time units can be lengthened or shortened in each bit. In order to compensate for the phase offset between the clock oscillators of the different bus controllers, any bus controller must be resynchronized at the edge of the associated signal currently being transmitted; the synchroniza-

tion jump width defines the maximum number of clock cycles that can be shortened or extended per each bit cycle.

$t_{SJW} = t_{SCL} \times (SJW + 1)$; Time period 1 (TSEG1) and Time period 2 (TSEG2) determine the number of clocks per bit and the position of the sampling point, where:

$t_{SYNCSEG} = 1 \times t_{SCL}$

$t_{TESG1} = t_{SCL} \times (TESG1 + 1)$

$t_{TESG2} = t_{SCL} \times (TESG2 + 1)$

A valid jump is defined as the first transition from a dominant bit to a recessive bit when CAN sends no recessive bit. If a valid jump is detected during Time period 1 (t_{TSEG1}) instead of the synchronization segment ($t_{SYNCSEG}$), the time of t t_{TSEG1} will be extended as long as SJW, and the sampling point will be delayed.

Conversely, if a valid jump is detected in Time period 2 (t_{TSEG2}) instead of $t_{SYNCSEG}$, then the time of t_{TSEG2} will be shortened by up to SJW, so that the sampling point is moved earlier.

As a safeguard against programming errors, the configuration of the Bit Timing Register (CAN_BTR) is only possible while CAN is in Standby mode.

CAN baud rate = APB1 /(2*(BRP + 1)*(TSEG1 + 1 + TSEG2 + 1 + 1)).

21.5.9 Arbitration lost

In case of arbitration lost, a corresponding arbitration lost interrupt (interrupt enable) is generated. At the same time, the current bit of the bit stream processor is captured and sent to the arbitration lost capture register. The contents of the register will not change until the user reads this value through software. Then, the capture mechanism is then activated again.

When the interrupt register is read, the corresponding interrupt flag bit in the interrupt register is cleared. The new arbitration lost interrupt is not valid until the arbitration lost capture register is read once.

The figure below explains the arbitration lost bits:

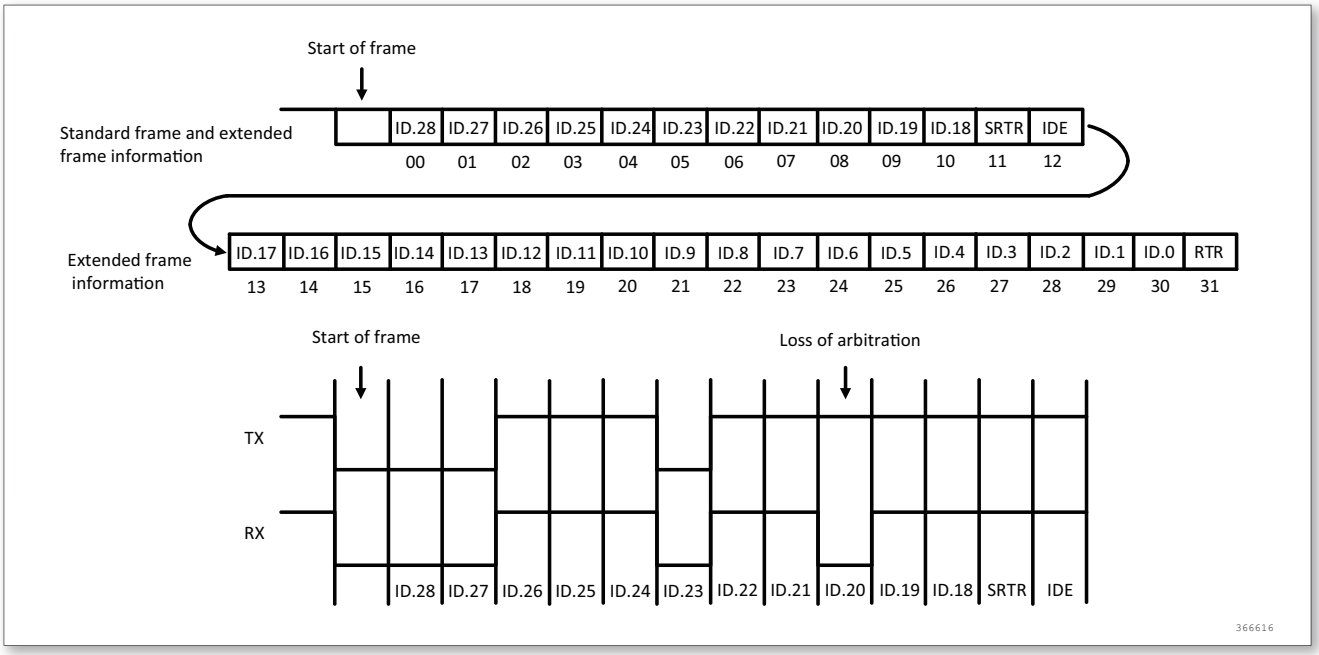

Figure 243. Example of Arbitration lost Interpretation

21.5.10 CAN interrupts

Four interrupts are dedicated to the BasicCAN mode:

- Receive interrupt
  It occurs when the receive FIFO is not null and the receive interrupt is enabled (CAN_CR register bit 1), and the RI bit of the CAN_IR register is set to ’1’.
- Transmit interrupt
  It occurs when the transmit buffer status changes from 0 to 1 (release) and the transmit interrupt is enabled (CAN_CR register bit 2).
- Error interrupt
  This bit is set due to the change in the error status bit or the bus status bit when the error interrupt is enabled (CAN_CR register bit 3).
- Data overrun interrupt
  It toggles to the data overrun status bit ’0 - 1’ when the data overrun interrupt enable bit (CAN_CR register bit 4) is set to ’1’.

Seven interrupts are dedicated to the PeliCAN mode:

- Receive interrupt
  It occurs when the receive FIFO is not null and the RIE bit of the interrupt register is set.
- Transmit interrupt
  It occurs when the transmit buffer state jumps from ’0 - 1’ (release) and the TIE bit of the interrupt register is set.
- Error warning interrupt
  It occurs when the error status bit and the bus status bit are changed and the EIE bit of the interrupt register is set.
- Data overrun interrupt
  It occurs when the data overrun status bit jumps from ’0 - 1’ and the DOIE bit of the

interrupt register is set.

- Error Passive interrupt
  It occurs when the CAN controller reaches the Error Passive state (at least one error counter exceeds the value (127) specified by the protocol) or changes from the Error Passive state to the Error Active state and the EPIE bit of the interrupt register is set.
- Arbitration lost interrupt
  It occurs when the CAN controller loses the arbitration and acts as a receiver and ALIE of the interrupt enable register is set.
- Bus error interrupt
  It occurs when the CAN controller detects a bus error and the BEIE in the interrupt enable register is set.

21.6 Description of CAN register

Res.												AFM	STM	LOM	RM
												rw	rw	rw	rw

Bit	Field	Type	Reset	Description
31 : 4	Reserved			Reserved, always read as 0.
3	AFM	rw	0x00	Acceptance filter mode 1: Single; select a single acceptance filter (32-bit length) 0: Dual; select two acceptance filters (each with 16 bits active)

Bit	Field	Type	Reset	Description
2	STM	rw	0x00	Self test mode 1: Self-test mode: all nodes can be detected, and no self-receive command is used for the active node; even if there is no response, the CAN controller will send message successfully. 0: Normal mode: acknowledgement signal must be sent in case of successful transmission
1	LOM	rw	0x00	Listen only mode 1: Listen only mode: the CAN controller sends no acknowledgement signal to the bus even if the message is successfully received; the error counter stops at the current value. 0: Normal mode
0	RM	rw	0x01	Reset mode 1: Reset mode: detect that the reset mode bit is set, then abort the information currently being received/transmitted, to enter the reset mode. 0: Normal mode: the CAN controller returns to the operating mode after the reset mode bit receives a '1-0' jump.

21.6.2 CAN control register(CAN_CR)

BasicCAN mode only

Address offset: 0x00

Reset value: 0x0000 0001

The contents of the control register are used to change the behavior of the CAN controller. These bits can be configured or set by the microcontroller, which enables read/write the control registers.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

											rw	rw	rw	rw	rw

Bit	Field	Type	Reset	Description
31 : 5	Reserved			Reserved, always read as 0.

Bit	Field	Type	Reset	Description
4	OIE	rw	0x00	Overflow interrupt enable 1: Enabled: if the data overflow bit is set, the microcontroller receives the overflow interrupt signal 0: Disabled: the microcontroller receives no overflow interrupt signal from the CAN controller
3	EIE	rw	0x00	Error interrupt enable 1: Enabled: if the error or bus status changes, the microcontroller receives the error interrupt signal 0: Disabled: the microcontroller receives no error interrupt signal from the CAN controller
2	TIE	rw	0x00	Transmit interrupt enable 1: Enabled: when the message is successfully transmitted or the transmit buffer is accessed again (for example, after aborting the send command), the microcontroller receives a transmit interrupt signal from the CAN controller 0: Disabled: the microcontroller receives no transmit interrupt signal from the CAN controller
1	RIE	rw	0x00	Receive interrupt enable 1: Enabled: when the message is received corretly, the CAN controller sends a receive interrupt signal to the microcontroller. 0: Disabled: the microcontroller receives no receive interrupt signal from the CAN controller
0	RR	rw	0x01	Reset request 1: Current: after detecting the reset request, the CAN controller aborts the information currently transmitted/received and enters the reset mode. 0: Null: After the reset request bit receives a falling edge, the CAN controller returns to the operating mode

21.6.3 CAN control register(CAN_CMR)

Address offset: 0x04

Reset value: BasicCAN mode: 0x0000 00FF

PeliCAN mode: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.											SRR	CDO	RRB	AT	TR
											w	w	w	w	w

Bit	Field	Type	Reset	Description
31 : 5	Reserved			Reserved, always read as 0.
4	SRR	w		PeliCAN mode: SRR: Self reset request 1: Current information can be sent and received simultaneously 0: (Null)
3	CDO	w		Clear data overrun 1: Clear: clear data overrun status bit 0: No action The clear data overrrun command bit is used to clear the data overflow indicated by the data overrun status bit. If this bit is set, no data overrun interrupt will be generated. The clear data overrun command can be issued while the receive buffer command is released.
2	RRB	w		Release receive buffer 1: Release: the memory space in the receive buffer will be released 0: No action After reading the receive buffer, the microcontroller can release the memory space of the current information in the RXFIFO by setting the receive buffer bit to '1', possibly making another message in the receive buffer valid immediately, thus enabling another receive interrupt (enable condition). In case of no other available information, the receive interrupt will no longer be generated and the receive buffer status bit will be cleared.
1	AT	w		Abort transmission 1: Current: if it is not in the process, the send request of waiting process will be canceled 0: Null: no action The abort transmission bit is used when the CPU requests the current transfer to be paused, for example, to send an emergency message, the ongoing transfer will not be stopped. In order to check if the original message is successfully sent, it can be detected with the successful transmit status bit, provided that, the transmit buffer status bit is 1 (release) or a transmit interrupt is generated.

Bit	Field	Type	Reset	Description
0	TR	w		Transmission request 1: Current: information is sent 0: Null: no action If the transmission request is set in the previous command, it cannot be canceled by setting it directly to 0 but by setting the abort transmission bit to 0.

21.6.4 CAN status register(CAN_SR)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.								BS	ES	TS	RS	TCS	TBS	DOS	RBS
								rw	rw	rw	rw	rw	rw	rw	rw

Bit	Field	Type	Reset	Description
31 : 8	Reserved			Reserved, always read as 0.
7	BS	rw	0x00	BS: Bus status 1: Bus-off: the CAN controller disables the bus activity 0: Bus-on: the CAN controller enables the bus activity When the transmission error counter exceeds the limit (255) (bus status bit set to ’1’ - bus off), the CAN controller will set the reset request bit to ’1’ (current); if allowable, the error interrupt will be generated. This state continues until the CPU clears the reset request bit. After that, the CAN controller will wait for the minimum time specified by the protocol (128 bus idle signals). After the bus status bit is cleared (bus on), the error status bit is set to ’0’ (ok), the error counter is reset and an error interrupt is generated (interrupt enable).
6	ES	rw	0x00	Error status 1: Error; at least one error counter is full or overflows CPU alarm limit 0: ok: both error counters are below the alarm limit According to the CAN 2.0B protocol, an error detected during reception or transmission affects the error count. The error status bit is set when at least one error counter is full or the CPU warning limit (96) is exceeded. If allowed, an error interrupt will be generated.

Bit	Field	Type	Reset	Description
5	TS	rw	0x00	Transmit status 1: Transmit: the CAN controller is transmitting information 0: Idle: no information is being sent If both the receive status bit and the transmit status bit are 0, the CAN bus is idle.
4	RS	rw	0x00	Receive status 1: Receive: the CAN controller is receiving information 0: Idle: no information is being received If both the receive status bit and the transmit status bit are 0, the CAN bus is idle.
3	TCS	rw	0x00	Transmission complete status 1: Completed: the last request is successfully processed 0: Not completed: the current transmission request has not been processed Whenever the transmission request bit is set to '1', the transmission complete bit will be set to '0' (not completed). The '0' of the transmission complete bit will remain until the message is successfully sent.
2	TBS	rw	0x00	Transmit buffer status 1: Released: the CPU is allowed to write information to the transmit buffer 0: Locked: the CPU is not allowed to access the transmit buffer; the information is waiting to be sent or being sent If the CPU attempts to write to the transmit buffer when the transmit buffer status bit is 0 (locked), the written byte is rejected and will be lost without any prompt.
1	DOS	rw	0x00	Data overrun status 1: Overrun: the information is lost since there is no enough space in RXFIFO to store it 0: Null: no data overrun occurrs since the last clear data overrun command is executed When the information to be received is successfully processed by the acceptance filter (for example, at the beginning of arbitration), the CAN controller requires some space in the RXFIFO to store the descriptor of this information. Therefore, enough space shall be configured, to store every data byte received. In case of insufficient space, the information will be lost and only the CPU will receive the prompt of data overflow; if the received message has no errors except the last bit, the message is valid.

Bit	Field	Type	Reset	Description
0	RBS	rw	0x00	Receive buffer status 1: Full: available information in RXFIFO 0: Null: no information available This bit is cleared after the information in the RXFIFO is read and the memory space is released with the release receive buffer command. If there is still information available in the FIFO, this bit will be reset in the next time limit (t_{SCL}).

21.6.5 CAN interrupt register(CAN_IR)

Address offset: 0x0C

Reset value: 0x0000 0000

The interrupt register allows to identifying the interrupt source; the interrupt is eanbled when one or more bits of the register are set; the interrupt register acts as a read-only memory for the microcontroller.

Bit	Field	Type	Reset	Description
1	TIE	rw	0x00	Transmit interrupt enable 1: Enabled: when the message is successfully transmitted or the transmit buffer is accessible (for example, after aborting the transmit command), the CAN controller will enable the corresponding interrupt. 0: Disabled
0	RIE	rw	0x00	Receive interrupt enable 1: Enabled: when the receive buffer status is 'full', the CAN controller will enable the corresponding interrupt. 0: Disabled

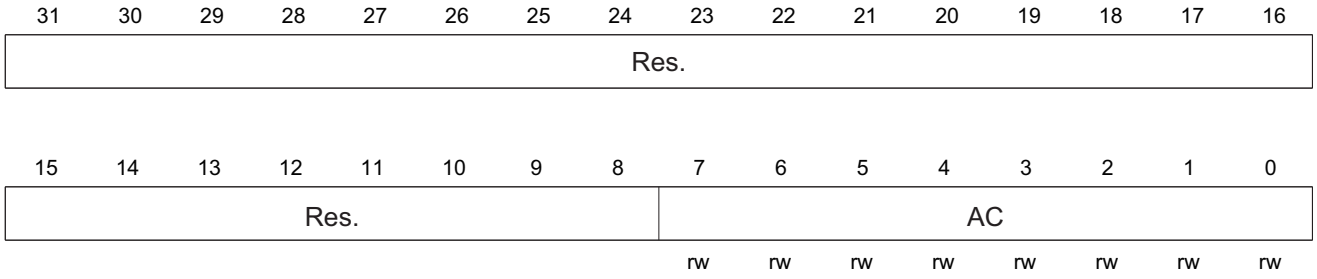
21.6.7 CAN acceptance code register(CAN_ACR)

BasicCAN mode: CAN_ACR

Address offset: 0x10

Reset value: 0x0000 00XX

With the acceptance filter, the CAN controller allows the RXFIFO to receive only the information that is consistent with the preset values in the identifier and the acceptance filter. The acceptance filter is defined by the acceptance code register and the acceptance mask register.



Bit	Field	Type	Reset	Description
31 : 8	Reserved			Reserved, always read as 0.

Bit	Field	Type	Reset	Description
7 : 0	AC	rw	0xXX	Acceptance code: This register is accessible (read/write) when the reset request bit is tied high (current). If a message passes the acceptance filter test and the receive buffer has enough space, the descriptor and data are written to the RXFIFO in sequence. When the information is received correctly: Receive status bit is set to high (full) Receive interrupt enable bit is set to high (enable) Receive interrupt is set to high (interrupt enabled) The acceptance code bit (AC.7-AC.0) is equal to the upper 8 bits of the message identifier (ID.10-ID.3), with OR relationship (1) to the corresponding bit of the acceptance mask bit (AM.7-AM.0). Namely, it is received if the following equation is satisfied: $[(ID.10-ID.3)\equiv(AC.7-AC.0)]\vee(AM.7-AM.0)\equiv11111111$

PeliCAN mode: There are four acceptance code registers: CAN_ACR0, CAN_ACR1, CAN_ACR2, CAN_ACR3

CAN_ACR0: Address offset: 0x40

Reset value: 0x00XX

CAN_ACR1: Address offset: 0x44

Reset value: 0x00XX

CAN_ACR2: Address offset: 0x48

Reset value: 0x00XX

CAN_ACR3: Address offset: 0x4C

Reset value: 0x00XX

Note: See the description of the peliCAN mode in the identifier filtering.

21.6.8 CAN acceptance mask register(CAN_AMR)

BasicCAN mode: CAN_AMR

Address offset: 0x14

Reset value: 0x0000 00XX

Res.								AM							
								rw	rw	rw	rw	rw	rw	rw	rw

Bit	Field	Type	Reset	Description
31 : 8	Reserved			Reserved, always read as 0.
7 : 0	AM	rw	0xXX	Acceptance mask: This register can be accessed (read/write) if the reset request is high (current). The acceptance mask register defines the corresponding bit of the acceptance code register to be 'correlated' or 'effect-free' (i.e. any value) for the acceptance filter.

PeliCAN mode: There are four acceptance mask registers: CAN_AMR0, CAN_AMR1, CAN_AMR2, CAN_AMR3

CAN_AMR0: Address offset: 0x50

Reset value: 0x00XX

CAN_AMR1: Address offset: 0x54

Reset value: 0x00XX

CAN_AMR2: Address offset: 0x58

Reset value: 0x00XX

CAN_AMR3: Address offset: 0x5C

Reset value: 0x00XX

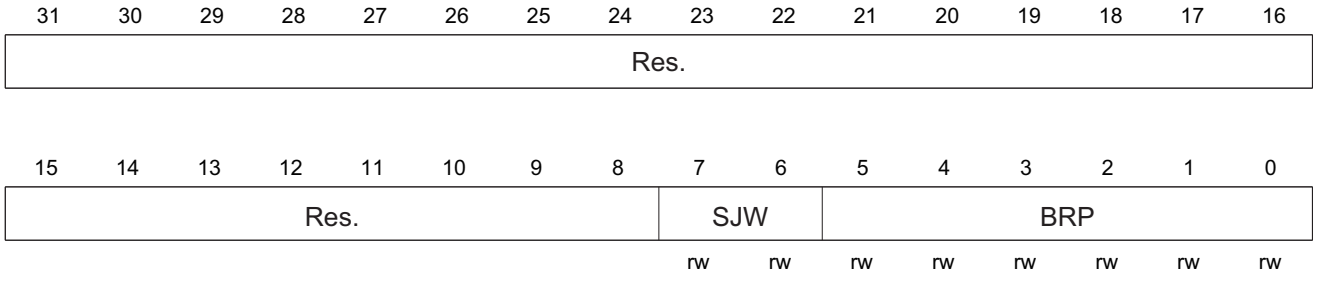
Note: See the description of the peliCAN mode in the identifier filtering.

21.6.9 CAN bus timing 0(CAN_BTR0)

Address offset: 0x18

Reset value: 0x0000 0000

Bus timing register 0 defines the baud rate preset (BRP) and synchronization jump width (SJW) values. This register can be accessed (read/write) when the reset mode is active.



Bit	Field	Type	Reset	Description
31 : 8	Reserved			Reserved, always read as 0.

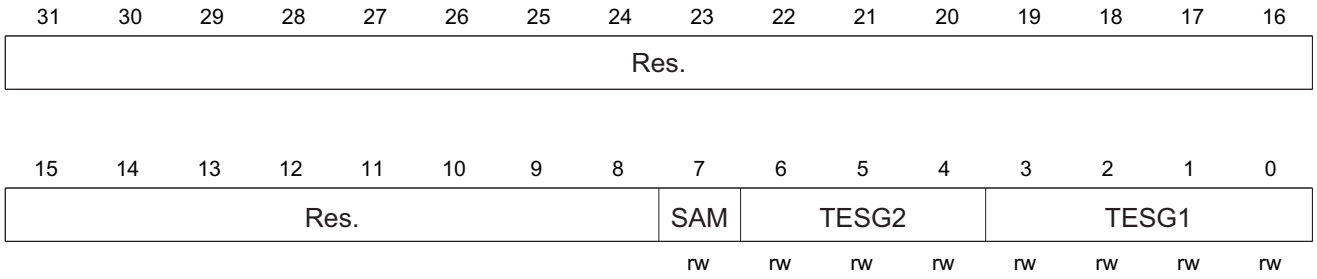
Bit	Field	Type	Reset	Description
7 : 6	SJW	rw	0x00	Synchronization jump width In order to compensate for the phase offset between the clock oscillators of the different bus controllers, any bus controller must be resynchronized at the edge of the associated signal currently being transmitted; the synchronization jump width defines the maximum number of clock cycles that can be shortened or extended per each bit cycle. $t_{SJW} = t_{SCL} \times (SJW + 1)$
5 : 0	BRP	rw	0x00	Baud rate prescaler The cycle of t_{SCL}, the CAN system clock, is programmable and determines the corresponding bit timing. The CAN system clock can be calculated by the following formula: $t_{SCL} = 2 \times t_{CLK} \times (BRP + 1)$ Where, t_{SCL} = the clock period of APB1

21.6.10 CAN bus timing 1(CAN_BTR1)

Address offset: 0x1C

Reset value: 0x0000 0000

Bus timing register 1 defines the length of each bit period, the location of the sampling points, and the number of samples at each sampling point. In the reset mode, this register allows read/write access.



Bit	Field	Type	Reset	Description
31 : 8	Reserved			Reserved, always read as 0.
7	SAM	rw	0x00	Sampling 1: Three times: the bus is sampled for three times; it is recommended to use the method on low/medium speed buses (A and B), which is beneficial for filtering the glitch on the bus. 0: Single: the bus is sampled once; the method is recommended on the high-speed bus (SAE C level)

Bit	Field	Type	Reset	Description
6 : 0	TSEG2 TSEG1	rw	0x00	Time segment 1 and Time segment 2 TSEG1 and TSEG2 determine the number of clocks per bit and the location of the sampling point, where: $t_{SYNCSEG}$ = 1 x t_{SCL} t_{TSEG1} = t_{SCL} × (8 × TSEG1.3 + 4 × TSEG1.2 + 2 × TSEG1.1 + TSEG1.0 + 1) t_{TSEG2} = t_{SCL} × (4 × TSEG2.2 + 2 × TSEG2.1 + TSEG2.1 + 1)

21.6.11 CAN transmit identifier register (CAN_TXID0)

In BasicCAN mode:

Address offset: 0x28

Reset value: 0x0000 00XX

Note: it is 0xFF in the reset mode

Transmit identifier register 0 defines the type and length of the transmitted frame, and enables read/write access only in the operating mode.

31 : 8	Reserved			Reserved, always read as 0.
7 : 0	IDx	rw	0xXX	CAN identifier byte 10 ~ 3 Note: In Peli mode, Bit [3:0] is DLC [3:0].

21.6.12 CAN transmit identifier register 1(CAN_TXID1)

Only applicable to BasicCAN mode:

Address offset: 0x2C

Reset value: 0x0000 00XX

Note: it is 0xFF in the reset mode.

Transmit identifier register 1 defines the type and length of the transmitted frame, and enables read/write access only in the operating mode.

Res.											BITNO				
											rw	rw	rw	rw	rw

Bit	Field	Type	Reset	Description
31 : 5	Reserved			Reserved, always read as 0.

Bit	Field	Type	Reset	Description
4 : 0	BITNO	rw	0x00	For values and functions, refer to the following table (Bit number) In case of arbitration lost, a corresponding arbitration lost interrupt (interrupt enable) is generated. At the same time, the current bit of the bit stream processor is captured and sent to the arbitration lost capture register. The contents of the register will not change until the user reads this value through software. Then, the capture mechanism is then activated again. When the interrupt register is read, the corresponding interrupt flag bit in the interrupt register is cleared. The new arbitration lost interrupt is not valid until the arbitration lost capture register is read once.

Table 72. Functions of Arbitration lost Capture Register's Bit 4 - Bit 0

Bit					Decimal value	Features
ALC.4	ALC.3	ALC.2	ALC.1	ALC.0		
0	0	0	0	0	0	Arbitration lost in Bit 1 of the identifier
0	0	0	0	1	1	Arbitration lost in Bit 2 of the identifier

Res.								ERRC		DIR	SEG				
								r	r	r	r	r	r	r	r

Bit	Field	Type	Reset	Description
31 : 8	Reserved			Reserved, always read as 0.
7 : 6	ERRC	r	0x00	Error code 00: Bit error 01: Format error 10: Padding error 11: Other errors
5	DIR	r	0x00	Direction 1: RX: error occurrs during reception 0: TX: error occurrs during transmission

Bit	Field	Type	Reset	Description
4 : 0	SEG	r	0x00	Segment Segment 00010: ID.28-ID.21 00011: Start of frame 00100: SRTR bit 00101: IDE bit 00110: ID.20-ID.18 00111: ID.17-ID.13 01000: CRC sequence 01001: Reserved bit 0 01010: Data field 01011: Data length code 01100: RTR bit 01101: Reserved bit 1 01110: ID.4-ID.0 01111: ID.12-ID.5 10001: Activity error flag 10010: Abort 10011: Dominant (control) bit error 10110: Error Passive flag 10111: Error delimiter 11000: CRC delimiter 11001: Acknowledge channel 11010: End of frame 11011: Acknowledge delimiter 11100: Overrun flag Other: reserved

Note: The bit configurations reflect different error events for the current structure segment.

When an error occurs on the bus, it is forced to generate a corresponding error interrupt (interrupt enabled). At the same time, the current position of the bitstream processor is captured and sent to the error code capture register. Its content is unchanged until the user reads it through the software. After reading, the capture mechanism is activated again. In the process of accessing the interrupt register, the corresponding interrupt flag bit in the interrupt register is cleared; the new bus interrupt is not active until the capture register is read once.

21.6.15 CAN error warning limit register(CAN_EWLR)

Only applicable to PeliCAN mode:

Offset address: 0x34

Reset value: 0x0000 0096

Error warning limits are defined in this register, with the default value (reset value) of 0x96. In the reset mode, this register is readable/writable to the CPU, and it is read-only in the operating mode.

Note: EWLR may only be changed if it has previously entered the reset mode. It is not possible to change the error state (see the Status Register) and the error warning interrupt caused by the contents of the new register until the reset mode is canceled again.

Res.								RXERR							
								rw	rw	rw	rw	rw	rw	rw	rw

Bit	Field	Type	Reset	Description
31 : 8	Reserved			Reserved, always read as 0.

Bit	Field	Type	Reset	Description
7 : 0	RXERR	rw	0x00	RX error counter register It reflects the current value of the receive error counter; the register is initialized to 0 after a hardware reset. In the operating mode, it is read-only to the CPU. This register can only be accessed by writing in the reset mode. The RX error counter is initialized to 0 if a bus-off condition occurs. Writing this register is not valid during bus-off. Note: It is only possible to force the RX error counter to change by the CPU before entering the reset mode. The error status change (see Status Register), error warning, and error interrupts caused by the contents of the new registers may be invalid until the reset mode is canceled.

21.6.17 CAN TX error count register(CAN_TXERR)

Only applicable to PeliCAN mode:

Offset address: 0x3C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.								TXERR							
								rw	rw	rw	rw	rw	rw	rw	rw

Bit	Field	Type	Reset	Description
31 : 8	Reserved			Reserved, always read as 0.

Bit	Field	Type	Reset	Description
7 : 0	TXERR	rw	0x00	TX error counter register It reflects the current value of the transmit error counter. In the operating mode, this register is a read-only memory to the CPU; accessing this register is only possible in the reset mode, and the register is initialized to 0 after a hardware reset. If the bus is off, the TX error counter is initialized to 127, to calculate the minimum time defined by the bus (128 bus idle signals). Reading the TX error counter during this time will reflect the status information of the bus-off recovery. If the bus-off is active, the bus off flag will be cleared in the 0 ～254 unit of write access TXERR, and the controller waits for an 11-bit continuous hidden (weak) bit (bus idle) after the reset mode is cleared. Writing 255 to TXERR will initiate a bus-off event for the CPU driver. It is only possible to change the contents of the TX error counter caused by the CPU before entering the reset mode. Until the reset mode is canceled again, an error or bus status change (see status register), an error warning, and an error interrupt caused by the contents of the new register may be invalid. After exiting from the reset mode, like the cause of bus error, the new contents of TX counter is given and the bus-off is enabled by the same way, which means that the reset mode is enabled again, the TX error counter is initialized to 127, the RX counter is cleared, and all status and interrupt register bits concerned are set. The protocol-defined bus-off recovery sequence (waiting for 128 bus idle signals) can be performed by clearing the reset mode. If the reset mode is enabled before the bus is off (TXERR > 0), the bus-off status remains active and TXERR is locked.

21.6.18 CAN transmit frame information register(CAN_SFF)

Only applicable to PeliCAN mode:

Offset address: 0x40

Reset value: 0x0000 000X

The transmit frame information register sets the type of the frame to be sent and the data length. This register can be read/written only in the operating mode, and acts as the transmit register when being written, and as the receive register when being read, with the same data structure.

22 Universal serial bus full-speed device interface(USB)

Universal serial bus full-speed device interface(USB)

22.1 USB introduction

The USB peripheral implements an interface between a full-speed USB 2.0 bus and the APB1 bus.

USB suspend/resume are supported which allows to stop the device clocks for low-power consumption.

22.2 USB main features

- USB specification version 2.0 full-speed compliant
- Support full-speed 12M mode
- One control transfer endpoint and four independent universal endpoints for interrupt transfer and bulk transfer.
- Up to 64 bytes of packets for control, bulk and interrupt transfer.
- Cyclic redundancy check (CRC) generation/checking, non-return-to-zero (NRZI) inverted coding/decoding and bit stuffing.
- USB suspend/resume operations
- DMA transfer

The following figure is a block diagram of the USB peripheral:

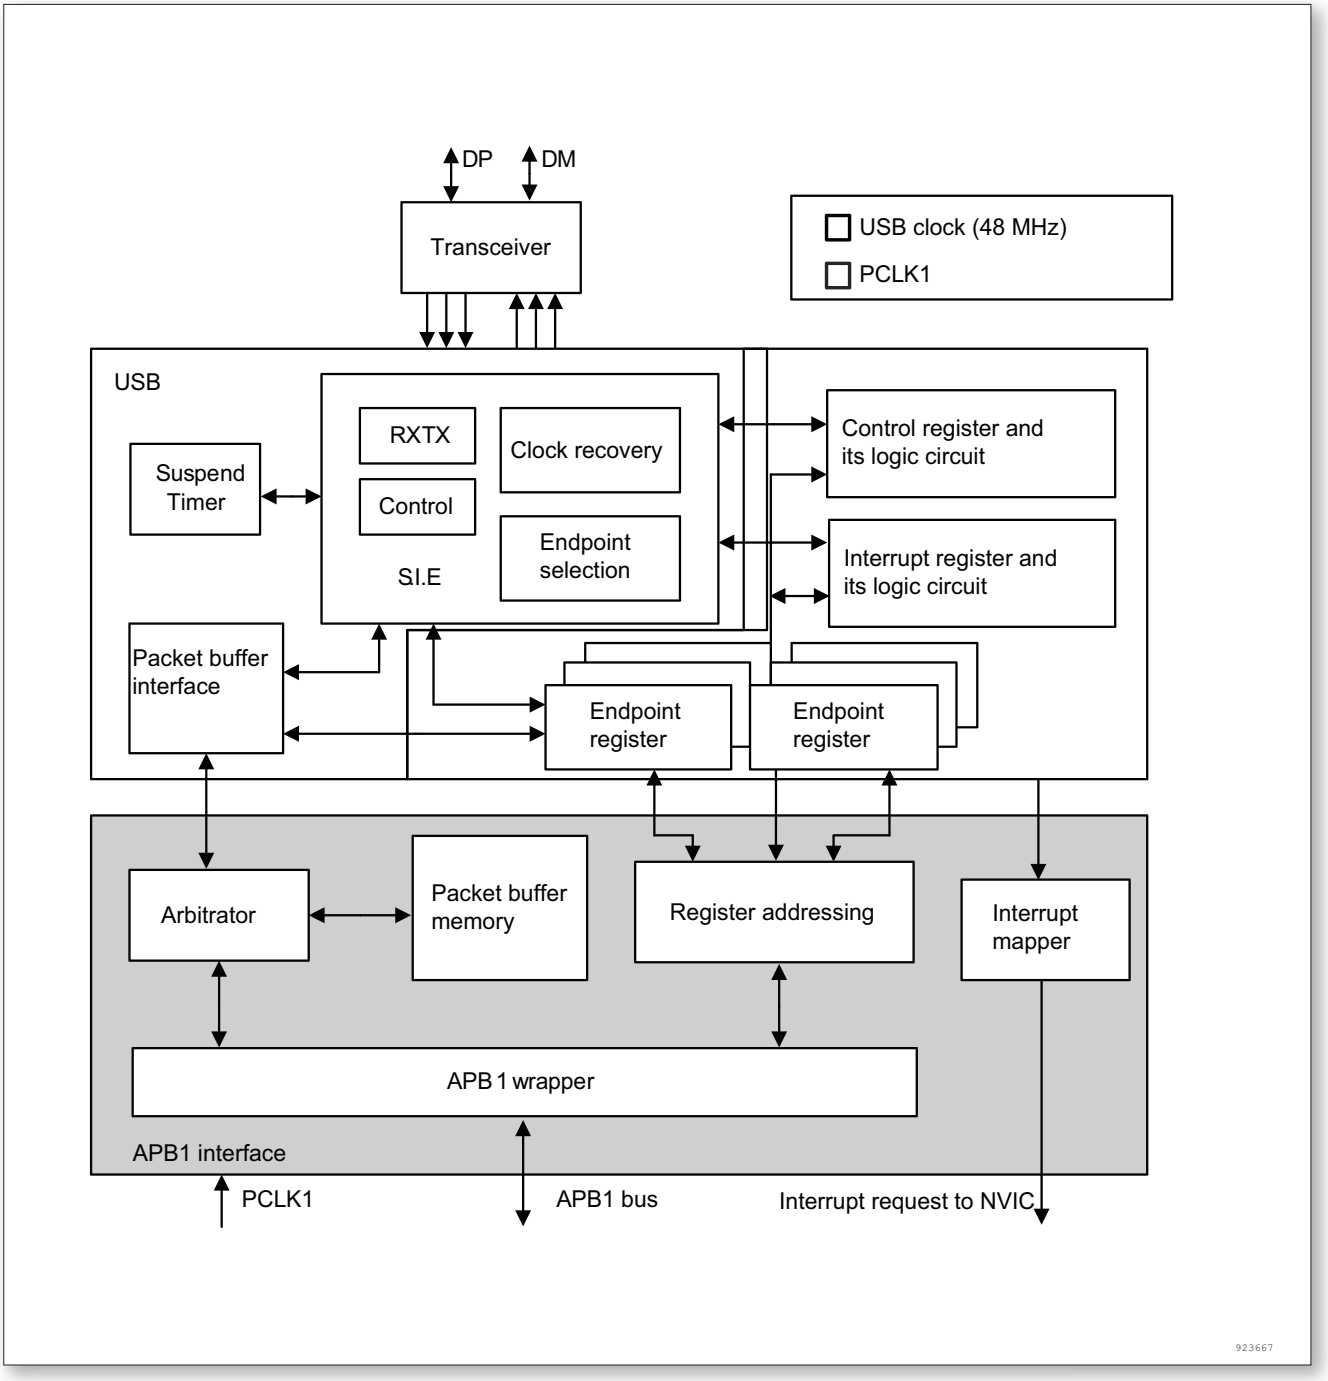

Figure 244. USB Block Diagram

22.3 Functional description

The USB peripheral provides an USB compliant connection between the host PC and the function implemented by the microcontroller. Data transfer between the host PC and the system memory occurs through a dedicated packet buffer memory accessed directly by the USB peripheral. The USB peripheral interfaces with the host PC, detecting token packets, handling data transmission/reception, and processing handshake packets as required by the USB standard. Transaction formatting is performed by the hardware, including CRC generation and checking.

Each endpoint is associated with a 64-bit buffer description block, and the buffer is located in the USB module and cannot be directly accessed by CPU. When a token for a valid function/endpoint pair is recognized by the USB peripheral, the related data transfer (if required and if the endpoint is configured) takes place. The data buffered by the USB peripheral is loaded in an internal register and memory access to the dedicated buffer is performed. When all the data has been transferred, if needed, the proper handshake packet over the USB is generated or expected according to the direction of the transfer.

At the end of the transaction, an endpoint-specific interrupt isgenerated, reading status registers and/or using different interrupt handling routines. The microcontroller can determine:

- Which type of transaction requested by the host
- Which endpoint has to be served
- What type of transmission is in process
- Endpoint response
- Whether the transmission is completed

The USB peripheral can be placed in low-power mode (SUSPEND mode) by writing the USB_POWER register whenever the peripheral is not required. At this time, all static power dissipation is avoided, and the USB clock can be slowed down or stopped. The detection of activity at the USB inputs, while in low-power mode, wakes the device up asynchronously. A special interrupt source can be connected directly to a wakeup line to allow the system to immediately restart the normal clock generation and/or support direct clock start/stop.

22.3.1 Description of USB blocks

The USB module contains an 8-bit wide 320-byte FIFO, with a 64-byte FIFO at endpoint. On the APB1 bus, each register uses the lower 8 bits of the 32-bit wide bus. In addition, data is stored through the lower 8 bits.

The USB module contains several registers:

- USB control register: used to configure USB parameters and query status
- Endpoint status register
- Endpoint configuration register
- Setup data register: used to store the data of the SETUP packet
- Endpoint data control register: used to control the data flow

The APB1 bus or DMA writes data or reads data to the data port, and the number of FIFO data increases or decreases accordingly.

The FIFO pointer changes only after the endpoint has successfully received and sent data. Each endpoint is configured with a FIFO data register that serves as the entry address for writing or reading FIFO. Each endpoint is also provided with a dedicated register, to query the current number of valid data in the FIFO.

Only Endpoint 1 and Endpoint 2 support DMA transfer.

22.4 Programming considerations

In the following sections, the expected interactions between the USB peripheral and the application program are described, in order to simplify application software development.

22.4.1 Overview of USB transmission

The following describes the relationship between packets, things, and transfer.

Packet is the basic unit of information transmission in a USB system. All data is transmitted on the bus after being packaged.

The basic USB packets are shown below, such as token packets, data packets, and handshake packets.

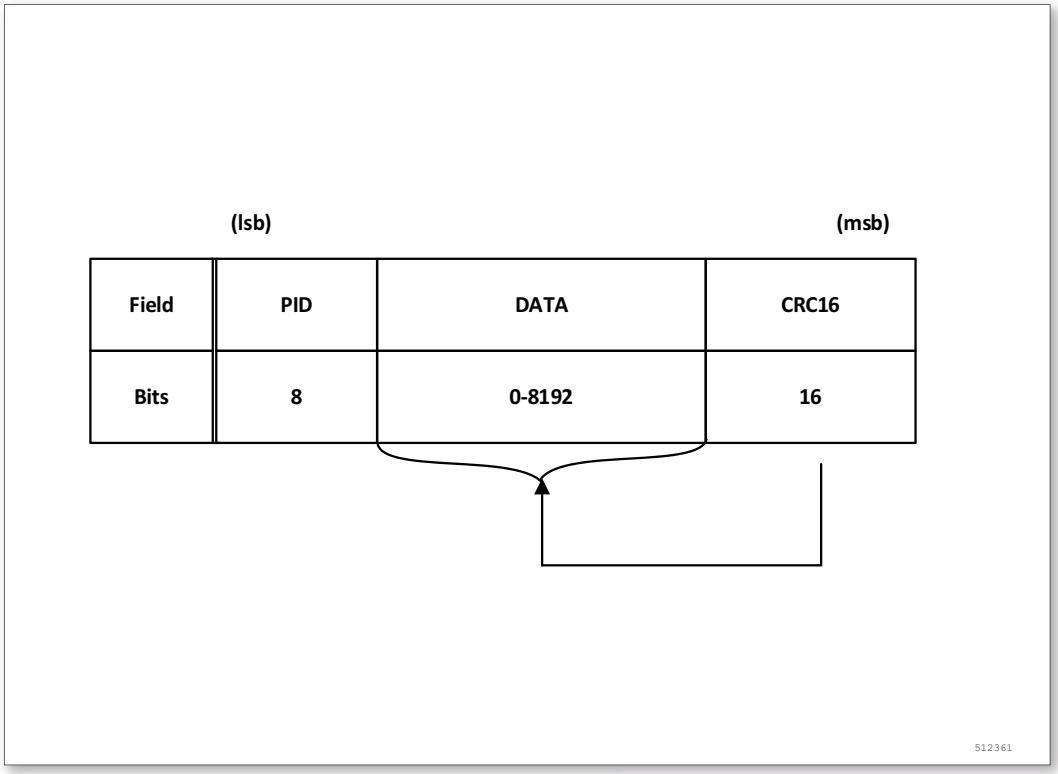

Figure 245. Basic Format of Packet

The process of receiving or transmitting data information on a USB is called a transaction. Types of transaction processing include input (IN) transaction processing, output (OUT) transaction processing, setup (SETUP) transaction processing, etc.

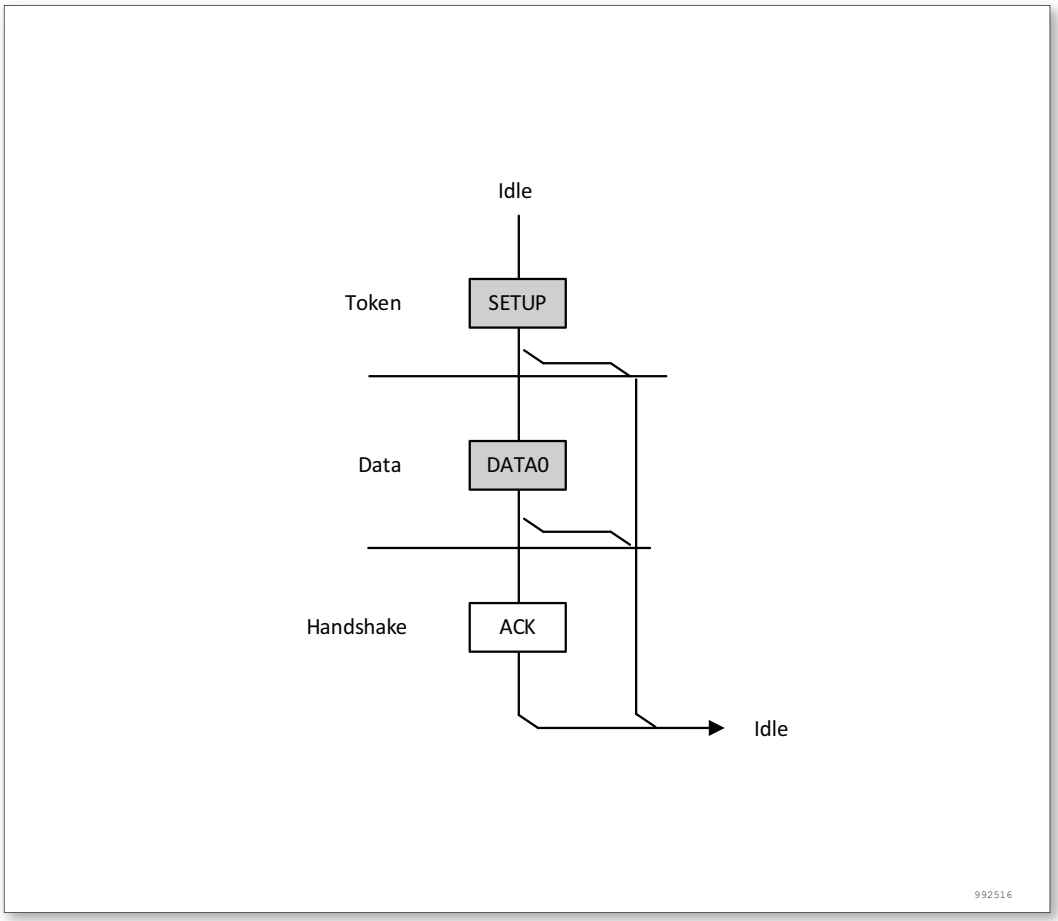

Figure 246. USB Transaction

The following figure depicts the complete transfer process of an endpoint. For bulk/control transfers, a transfer must begin after the last transfer.

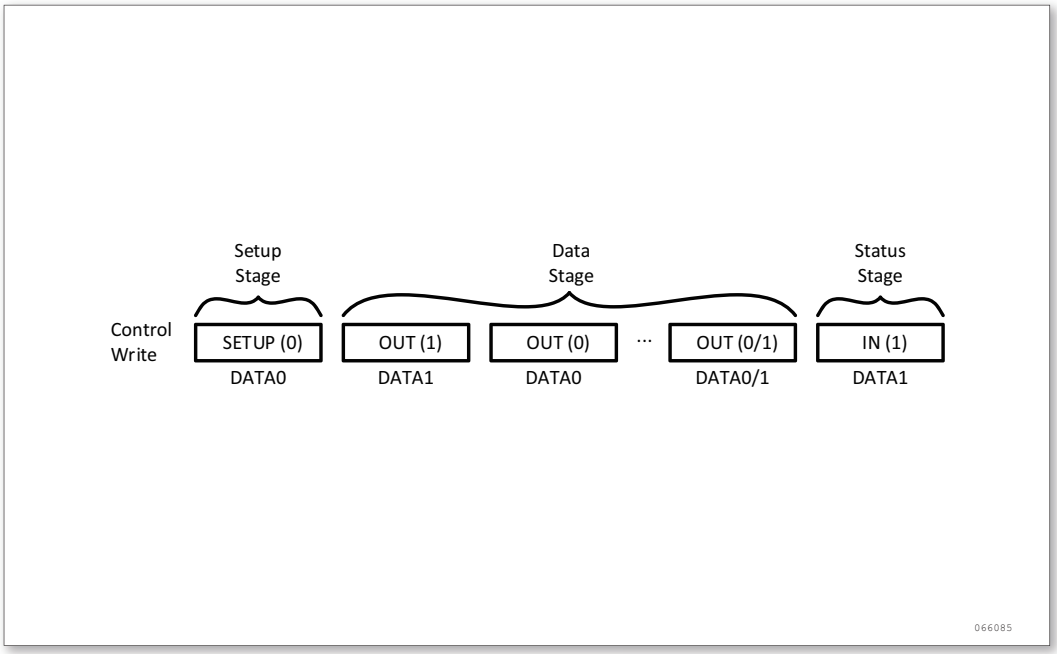

Figure 247. USB Transfer

When the USB controller starts working, the USB is in the IDLE state, and then waits for the bus command. After a bus command is received, such as reset, setup, etc., an interrupt is generated and the CPU queries the command type. For example, if it is a reset command, the CPU clears and resets all programmable states. If it is a transmission request command, the CPU will write/read the data in the USB controller FIFO. For bulk transfer or control transfer of input, when data is prepared in CPU or DMA, the CPU will send an ACK handshake signal or STALL handshake signal, to end the transfer. For the bulk transfer of output, the USB automatically sends an ACK signal when the data is transmitted to the corresponding FIFO.

When the data size exceeds the maximum packet size during transmission, the data is divided into more than one packets for transmission, otherwise, only one packet will be transmitted.

22.4.2 USB enumeration

The host sends various requests to the device through the Endpoint 0 in the manner of controlling the transmission. After receiving the request from the host, the device restores the corresponding information and performs enumeration.

After the system power-on and reset, configure the USB controller first:

1. Set the endpoint enable bit
2. Enable the reset and endpoint interrupt
3. Set the connect bit (CONNECT bit of the USB_TOP register)

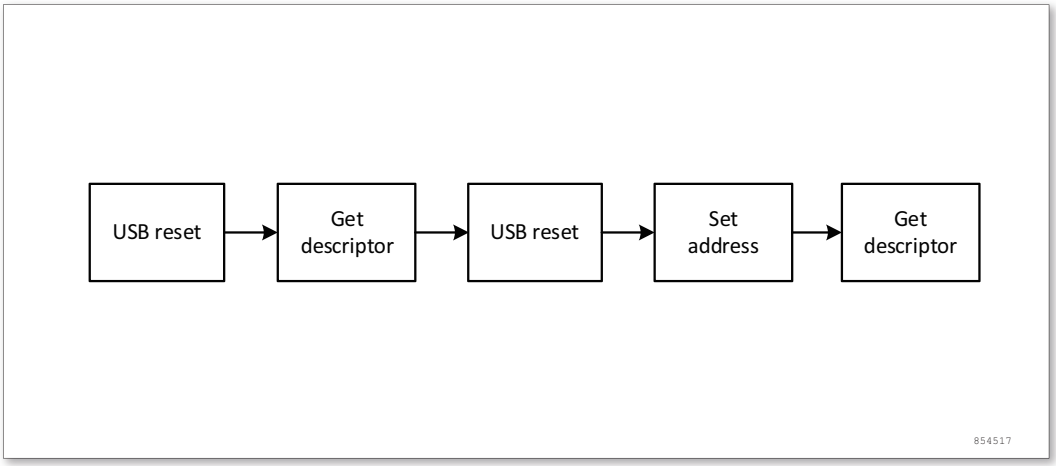

Figure 248. Enumeration Process

When Endpoint 0 receives the SETUP packet, the system will read the set 8 bytes of data, to determine the next step. For the SetAddress descriptor, the USB controller will automatically load the new address.

The analysis in the first cycle during enumeration covers:

The device is detected and the host sends a bus reset, which is different from USB power-on reset and system reset and is a reset that the SIE notifies the user according to the bus status. The device generates a reset interrupt and the device firmware program determines the handling method.

The host enables the first control transfer:

1. Host SETUP packet (to Address 0 and Endpoint 0), host packet (request device descriptor), device handshake packet ACK.
   The device generates an data output interrupt of Endpoint 0. The firmware program is prepared according to the host requirements in the packet, namely, the device descriptor is prepared in the input buffer of Endpoint 0.
2. Data process: the host sends an IN token packet first, and the device sends a data packet (this data is ready, the SIE receives the IN token and sends it directly to the bus; the user shall not intervene at this time), and the host sends an ACK packet.
   At this point, the SIE generates an data input interrupt of Endpoint 0, indicating that the host has got the data prepared by the device, and the user can also perform relevant operations in the interrupt handling routine (SIE refers to the serial interface engine, which is the 'core' of USB controllers. The SIE handles the underlying protocols such as bit stuffing, CRC generation and checking, and enables issuing error reports. Its main task is to convert low-level signals into bytes for the controller's application).
   At the moment, the host accepts only one data, at least 8 bytes. If the user data is not sent, and is stored in the control endpoint input buffer, the host will ignore it even if it has been prepared.
3. Status process: The host sends an OUT packet (notifying the device to output) and 0 byte status packet (this is 0 bytes, indicating that it received the device descriptor), and the device sends a handshake ACK packet.
   At this time, the device will not generate a data output interrupt of Endpoint 0, and there is no data.

During the enumeration, the address is set in the second cycle.

After the first cycle, the host resets the bus again, to enter the address setting control transfer phase.

1. Host SETUP packet (to address 0 and Endpoint 0), host packet (request setting address), device handshake packet ACK. So the SETUP packet will be followed by a data packet (either GET or SET) indicating the purpose of the host SETUP.
   The device generates a data output interrupt of Endpoint 0. The firmware program is prepared according to the host requirements in the packet, and the address control register is written according to the address sent by the host.
2. Data process: No data is transmitted.
3. Status process: The host sends an IN packet (notifying the device to return data), the device sends a 0 byte status packet (indicating that the address has been set successfully), and the host sends a handshake ACK packet (the address setting has taken effect).
   At this time, the device will not generate a data input interrupt of Endpoint 0, and there is no data.

During the enumeration, the host uses the new address to get the full device descriptor in the third cycle.

The host enables the first control transfer with the new address:

1. Host SETUP packet (to new Address endpoint 0), host packet (request device descriptor), device handshake packet ACK.
   The device generates an data output interrupt of Endpoint 0. The firmware program is prepared according to the host requirements in the packet, namely, the device descriptor is prepared in the input buffer of Endpoint 0.
2. Data process: the host sends an IN token packet first, and the device sends a data packet (this data is ready, the SIE receives the IN token and sends it directly to the bus; the user shall not intervene at this time), and the host sends an ACK packet.
   At this time the SIE generates a data input interrupt of Endpoint 0, indicating that the host has got the data prepared by the device. The user can perform the following operations in the interrupt handling routine: if the descriptor is not sent once, the remaining content is transmitted to the input buffer of Endpoint 0.
   The second data transmission: the host sends another IN token packet, the device sends a data packet, and the host sends an ACK packet.
   At the moment, SIE generates a data input interrupt of Endpoint 0 if the data has been sent (not processed here), to enter the status process.
3. Status process: The host sends an OUT packet (notifying the device to output) and 0 byte status packet (indicating that it received the device descriptor), and the device sends a handshake ACK packet.

22.4.3 USB transfer handling

The system needs to set up an inoperative loop, to wait for a request from the USB host, which sets an interrupt bit, and the system jumps out of the loop by constantly querying the interrupt bit or entering the interrupt service routine. When the system detects the interrupt bit, it jumps to the corresponding subroutine for processing.

The following figure is a flow chart of a typical USB transfer:

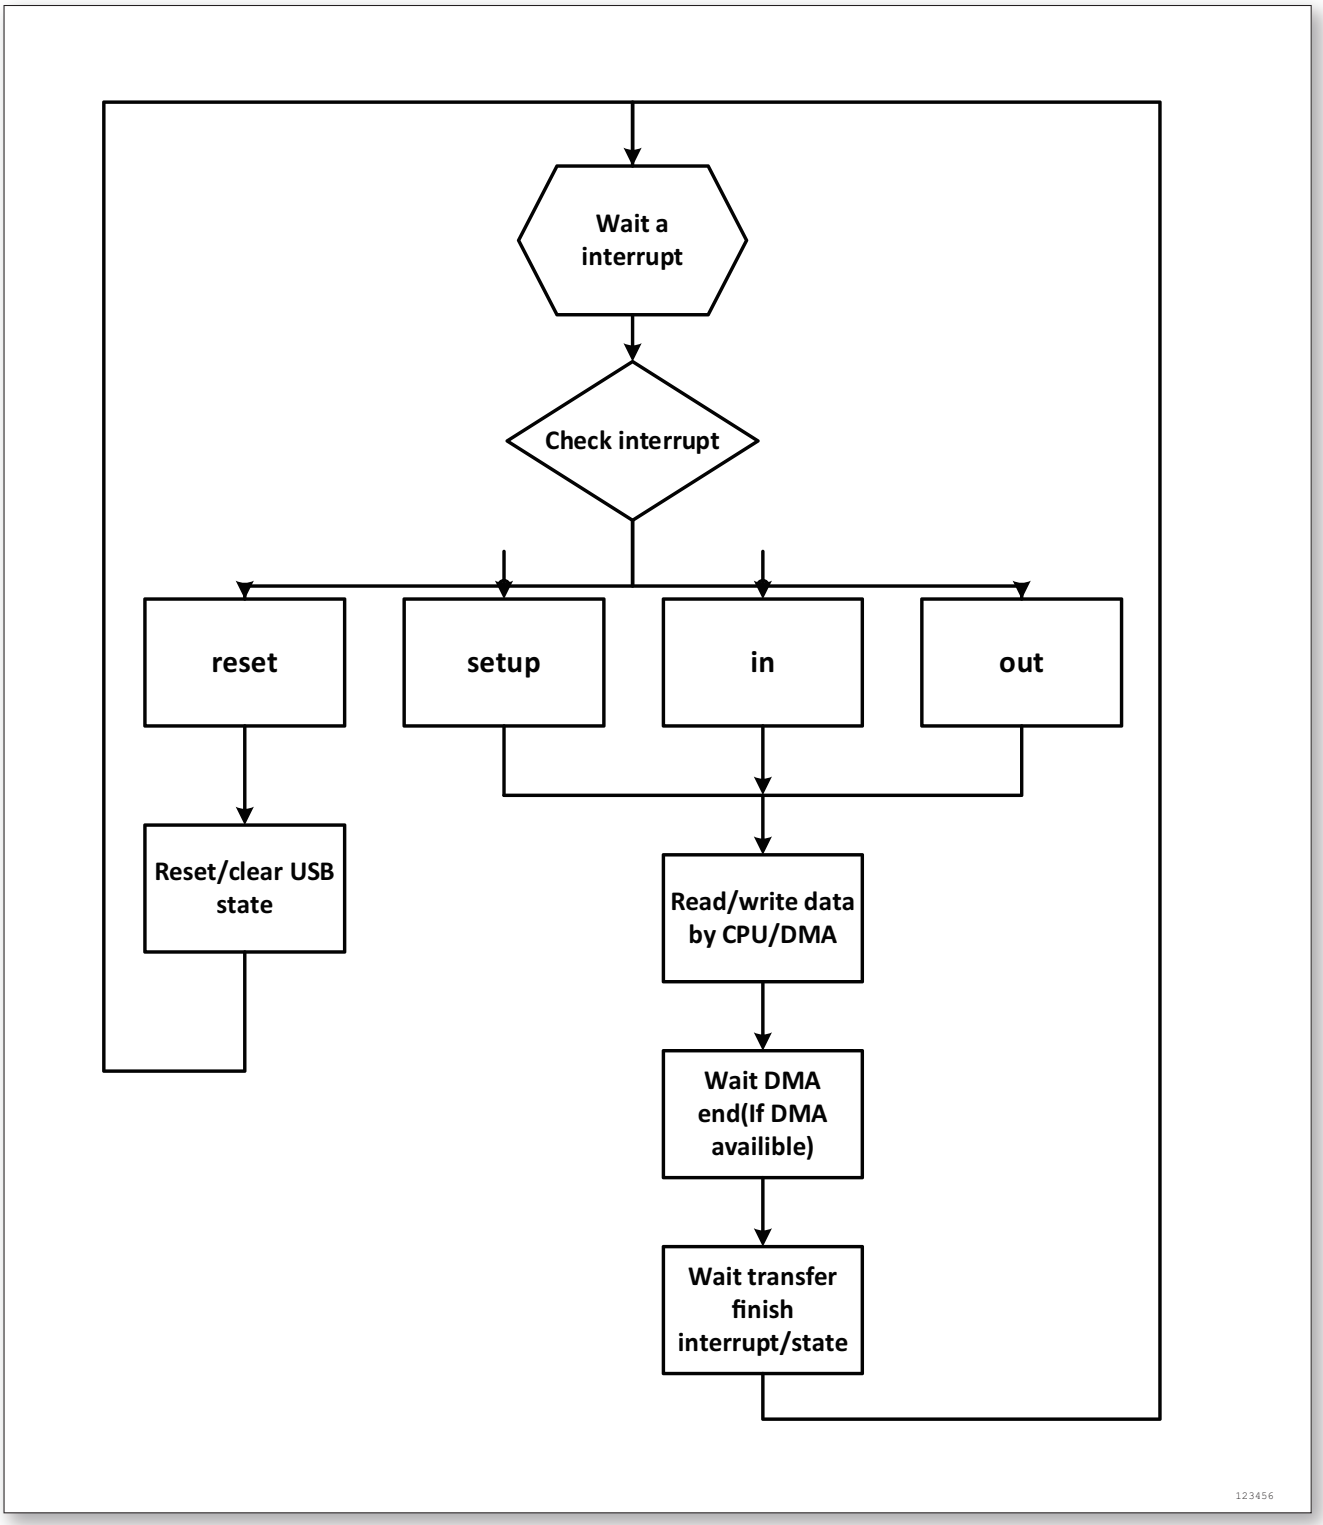

Figure 249. USB Transfer Flowchart

22.4.4 IN token packet

When receiving an IN request from a host, if a NACK response is received, the USB host resends the IN request until the endpoint confirms that the request is valid. If the received address matches a configured endpoint address, follow these steps:

1. If the data in the FIFO is less than the size set in register EPX_CTRL6:0, or EPX_CTRL7

is not set, the USB module will automatically send a NACK until the data is ready.

2. The CPU receives the IN_NACK status.
3. The CPU writes the data to the FIFO.
4. The CPU sets the size of the data to be sent and the transmit enable in the EPX_CTRL register.
5. The USB module automatically sends the data in the FIFO when receiving the next IN request. After the last data byte is sent, the calculated CRC is automatically transmitted.
6. The CPU receives the IN_ACK status and the END status after the transmission.
7. If the endpoint is not enabled, or if the EP_HALT register configuration is paused, the USB module will acknowledge IN_STALL without sending data.

22.4.5 OUT token packet

When receiving an OUT request from a host, if a NACK response is received, the USB host resends the OUT request until the endpoint confirms that the request is valid. If the received address matches a configured endpoint address, follow these steps:

1. If the space in the FIFO is less than the size of the packet sent by the host, the USB module will automatically send a NACK until the CPU fetches the data from the FIFO.
2. The CPU receives the OUT_NACK status.
3. The CPU reads data from the FIFO.
4. If the endpoint is not enabled, or if the EP_HALT register configuration is paused, the USB module will acknowledge OUT_STALL without sending data.

22.5 USB register description

Table 73. USB Register Overview

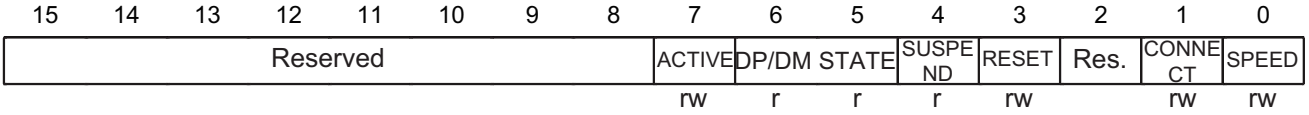
22.5.1 USB TOP register(USB_TOP)

Offset address: 0x00

Reset value: 0x0000 0002



Bit	Field	Type	Reset	Description
15 : 8	Reserved			Always read as 0.
7	ACTIVE	rw	0x00	USB bus is active 0：USB bus is inactive 1：USB bus is active
6 : 5	DP/DM STATE	r	0x00	Current USB DP/DM line state
4	SUSPEND	r	0x00	USB suspend state This bit monitors the controller status regardless of the APB_POWER register. 0: The controller is in an operating state 1: The controller is in a suspending state
3	RESET	rw	0x00	Reset EP and FIFO in USB controller 0: Not reset 1: Reset Note that this bit needs to be cleared by software after being set.
2	Reserved			Always read as 0.
1	CONNECT	rw	0x01	USB connection 0: Disconnected 1: Connected

Bit	Field	Type	Reset	Description
0	SPEED	rw	0x00	Set USB speed 0: Full speed transmission 1: Low speed transmission

22.5.2 USB interrupt status register(USB_INT_STATE)

Offset address: 0x04

Reset value: 0x0000 0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

23 Clock feedback system (CRS)

Clock feedback system (CRS)

23.1 Introduction

The clock feedback system (CRS) is an advanced digital controller that acts on the internal high-speed clock (HSI48), to calibrate the clock. By comparing the optional synchronous source, the CRS enables evaluating the oscillator's output frequency. By measuring the frequency error value, the CRS enables automatically calibrating the oscillator. Of course, it also supports manually calibration.

The CRS system is suitable for providing accurate clocks to USB peripherals. In the case when USB is used, the synchronous source comes from the SOF packet on the USB bus, and the SOF is sent by the USB host every 1mS.

The synchronization signal can also be provided by the LSE clock, an external pin or directly from the user software.

23.2 CRS main features

- Optional synchronous source (with programmable prescaler and polarity selection)
  - External pin
  - LSE clock output
  - USB SOF packet reception
- Synchronization pulse generated by software
- Separating from the CPU for automatical calibration
- Manual control option to initiate convergence faster
- 16-bit frequency error counter supporting automatic error capture and data loading
- Programmable limited frequency error assessment and status reporting
- Masking interrupts/events
  - Expected synchronization (ESYNC)
  - Synchronization correct (SYNCOK)
  - Synchronization warning (SYNCWARN)
  - Synchronization error or calibration error (ERR)

23.3 Functional description

23.3.1 CRS block diagram

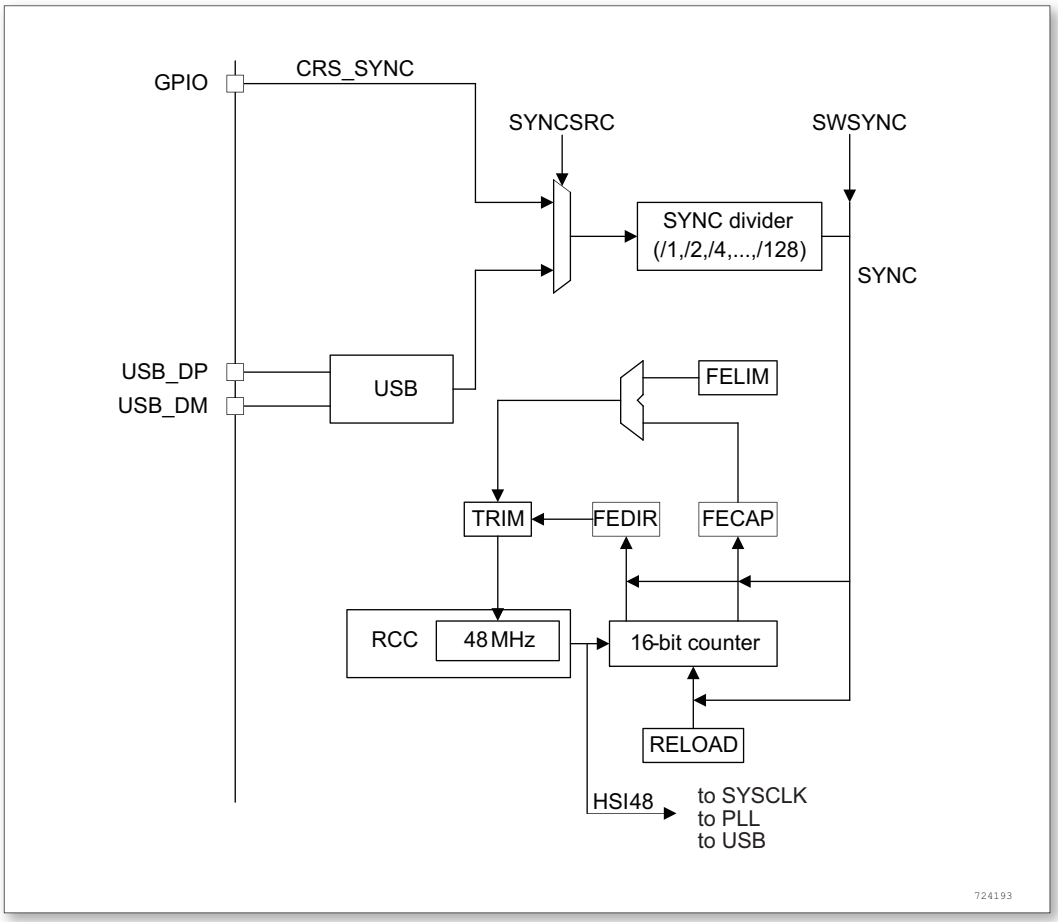

Figure 250. CRS block diagram

23.3.2 Synchronous input

The CRS synchronous source, configured through the CRS_CFGR register, comes from an external CRS_SYNC pin or a USB SOF packet. To realize the better robustness of the synchronous input source, a simple 2-level digital filtering sampled with HSI48 clock is essential, to filter minor errors.

The source has a configurable polarity and can be divided by a programmable prescaler, to keep it within a suitable frequency range (typically 1 kHz).

23.3.3 Frequency error measurement

The frequency error counter is a 16-bit upcounter/downcounter that loads the RELOAD value when an event is triggered. It starts counting down until 0, triggering the ESYNC (desired synchronization) event. Then, it starts counting up to the limit of OUT-RANGE, stops (if no SYNC event is received), and generates a SYNCMISS event. The limit value of OUTRANGE is obtained through multiplying the frequency error value (FELIM bit of the CRS_CFGR register) by 128.

When a synchronization event is detected, the actual value of the frequency error counter and the count direction are stored in the FECAP and FEDIR bits of the CRS_ISR register.

A synchronization event is detected during the counter's down counting phase (before reaching '0'), indicating that the actual frequency is below the target value (the TRIM value needs to be incremented). Conversely, a synchronization event is detected in the up counting phase, indicating that the actual frequency is higher than the target value (the TRIM value needs to be decremented).

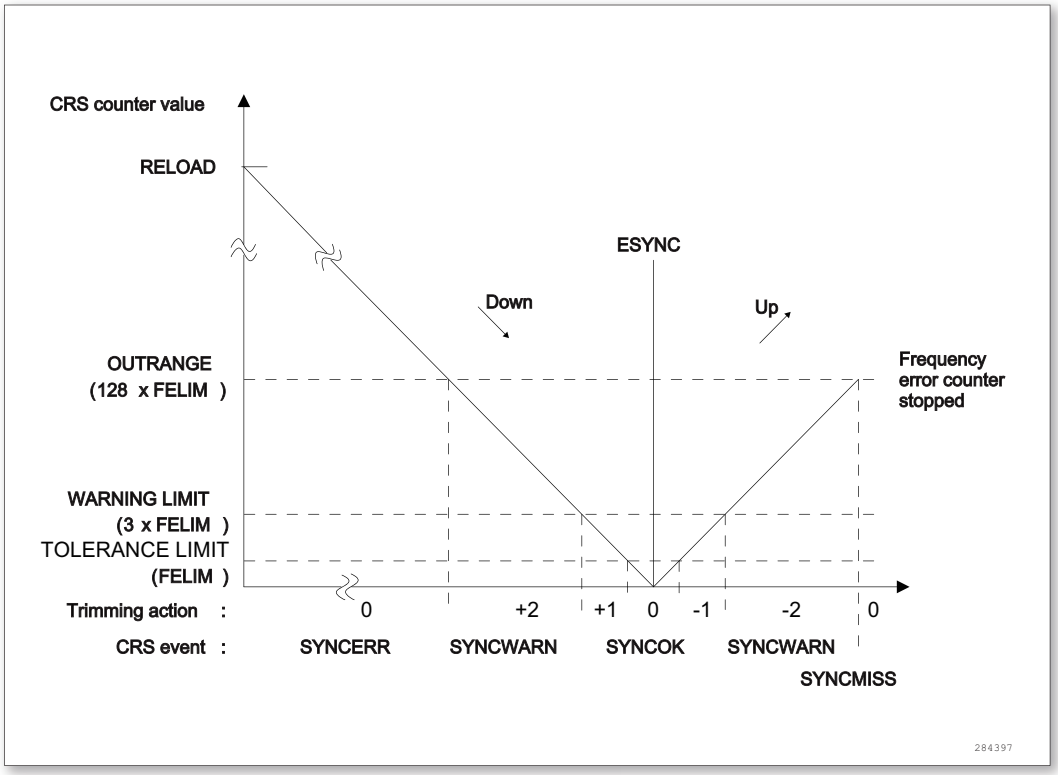

Figure 251. CRS Counter Status Diagram

23.3.4 Frequency error calculation and automatic calibration

The frequency error is evaluated by comparing the relationship between the measured value and each limit value:

- TOLERANCE LIMIT: fetched directly from the FELIM bit of the CRS_CFGR register
- WARNING LIMIT: Defined as 3*FELIM value
- ERROR LIMIT: defined as 128*FELIM value

The comparison result is typically used to generate a status flag and to control auto-calibration (if the AUTOTRIM bit in the CRS_CR register is enabled):

- When the frequency error is below the tolerance limit, the actual calibration value is within the ideal range, requiring no correction.
  - The synchronization correct flag (SYNCOK) is set.
  - In the automatic calibration (AUTOTRIM) mode, there is no need to correct the TRIM value.
- When the frequency error is below the warning limit and is greater than or equal to the tolerance limit, some calibration is required, and the regulator only needs to be adjusted to Shift 1, to reach the desired TRIM value.
  - The synchronization correct flag (SYNCOK) is set.

  - In the automatic calibration (AUTOTRIM) mode, the TRIM value is adjusted for one shift at a time.
- When the error count is greater than or equal to the warning limit but less than the error limit, great calibration is required and the next synchronization period will not reach the desired TRIM value.
  - The synchronization warning flag (SYNCOK) is set.
  - In the automatic calibration (AUTOTRIM) mode, the TRIM value is adjusted for two shifts at a time.
- When the error count is greater than or equal to the error limit, the frequency error is out of the calibratable range. This will also happen if the synchronization signal is not cleared or lost (for example: USB SOF packet lost).
  - The synchronization error (SYNCERR) or synchronization loss (SYNCMISS) flag is set.
  - In the automatic calibration (AUTOTRIM) mode, the TRIM value is unchanged.

Note: If the actual TRIM value is close to the boundary, continuing (automatic) calibration will cause the overflow of TRIM value, at this time, the TRIM value will be locked at the boundary and the calibration overflow (TRIMOVF) flag will be set.

In auto-calibration (AUTOTRIM) mode (configuring the CRT_CR register AUTOTRIM bit), the TRIM bit can only be configured by hardware and is read-only.

23.3.5 CRS initialization and configuration

Reload (RELOAD) value

RELOAD value is determined by comparing the target frequency with the divided frequency of the synchronized source, and the value is decremented by one each time so that it reaches the desired frequency at zero. The formula is as follows:

$$RELOAD = (f_{\text{TARGET}}/f_{\text{SYNC}}) - 1$$

The reset RELOAD value matches a 48 MHz target clock and a 1 KHz synchronization signal frequency (SOF signal from the USB).

FELIM value

The selection of FELIM requires a combination of the characteristics of the HSI48 and its typical adjustment shift. The ideal value corresponds to half of the adjustment step, expressed as the count of a series of HSI48 oscillators. The formula is as follows:

$$FELIM = (f_{\text{TARGET}}/f_{\text{SYNC}}) * STEP[\%]/100\%/2$$

In order to achieve better correction feedback, you shall always capture the nearest integer of the correction value. If you do not want to adjust the correction value frequently, you can increase the FELIM value appropriately.

The reset FELIM shall match ($f_{\text{TARGET}}/f_{\text{SYNC}}$)= 48000 and a typical adjustment shift (0.14%).

Note: A faulty RELOAD and FELIM configuration results in an unstable decrementing response and no hardware protection. The ideal mode of operation requires the appropriate RELOAD value setting (based on the frequency setting of the synchronization source) and the value of RELOAD is also 128 times greater than the FELIM value.

23.3.6 CRS flowchart

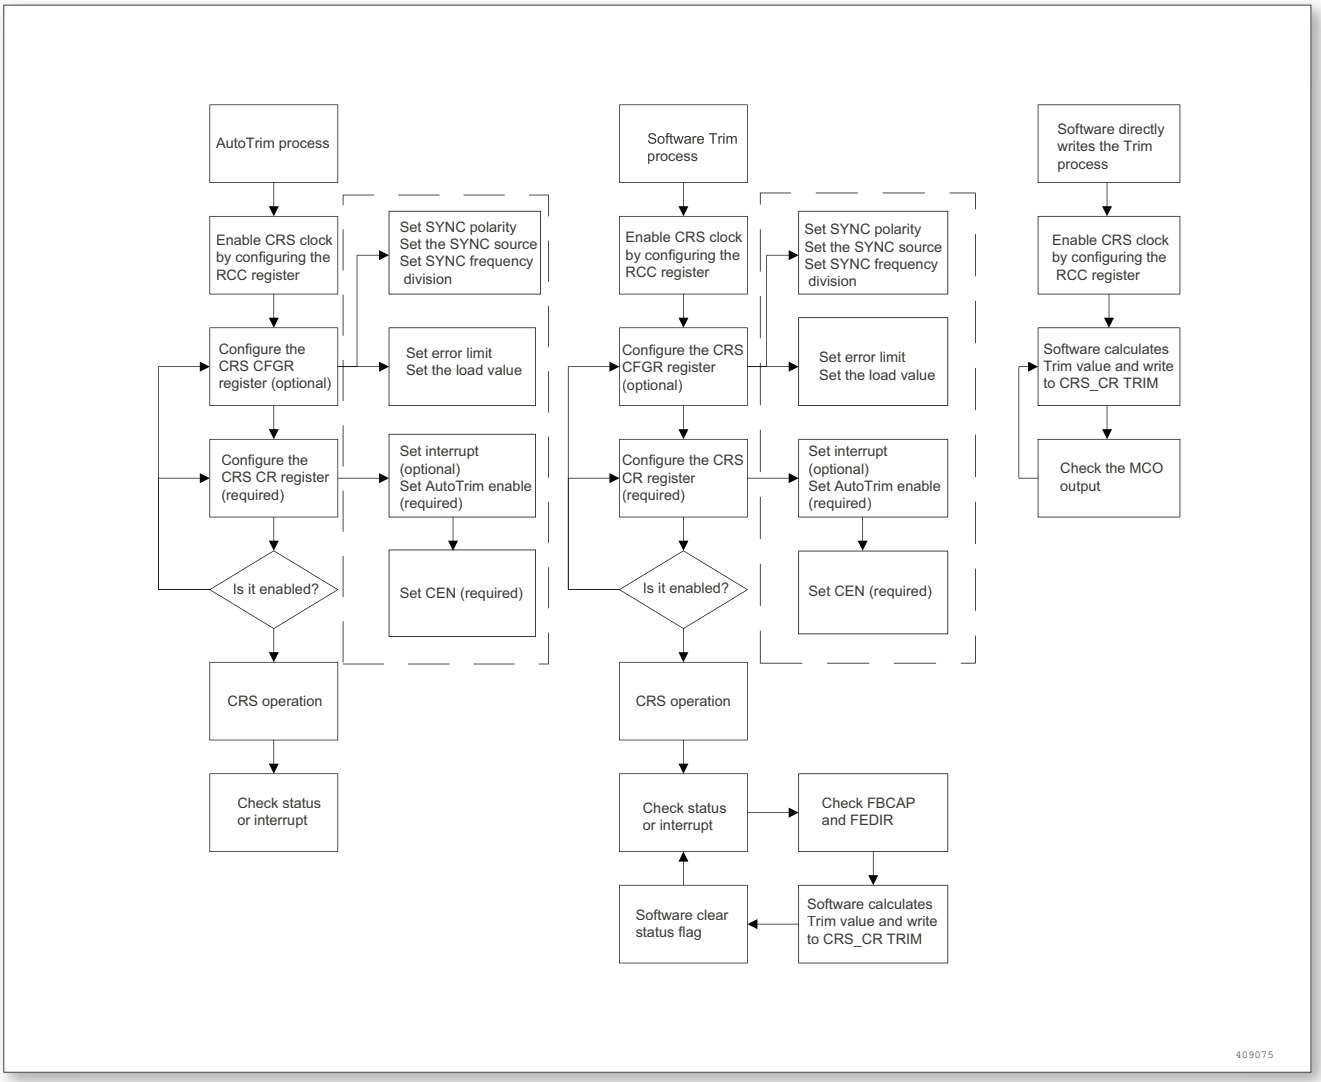

Figure 252. CRS block diagram

23.4 CRS Low-power mode

Table 74. Impact of CRS Low-power Mode

Mode	Description
Sleep	No effect,CRS's interrupt service routine will cause the device to exit from the Sleep mode.
Stop	The CRS register cannot be overwritten. The CRS stops operating until the Stop or Standby mode exits and the standby HSI48 oscillator is restarted.

14: 11	Reserved			Reserved, always read as 0.
10	TRIMOVF	r	0x00	Trimming overflow or underflow This flag is set by hardware when the automatic tirmming is to overflow or underflow. If the ERRIE bit of the CRS_CR register is set, an interrupt is generated. This bit is cleared by software setting the ERRC bit in the CRS_ICR register. 0: No tirmming error signal 1: Tirmming error signal generated
9	SYNCMISS	r	0x00	SYNC missed When the frequency error counter reaches 128 times FELIM and no SYNC event is triggered, it means that a SYNC pulse is lost or the frequency error is too big (internal frequency is too high) to be adjusted by regulating the TRIM value, requiring other measures, and SYNCERR will be set by hardware. In this case, the frequency error counter stops operating (waiting for the next SYNC). If the ERRIE bit of the CRS_CR register is set, an interrupt is generated, and the ERRC bit in the CRS_ICR register can be cleared by software. 0: No SYNC missed error signal 1: SYNC missed error signal generated
8	SYNCERR	r	0x00	SYNC error When the synchronization pulse is input, the measured frequency error is greater than or equal to 128 times the FELIM before the ESYNC behavior is triggered, and SYNCERR is set by hardware, it means that the frequency error is too big (internal frequency is too low) to be adjusted by regulating the TRIM value, requiring other measures. If the ERRIE bit of the CRS_CR register is set, an interrupt will be generated; the ERRC bit in the CRS_ICR register can be cleared by software. 0: No SYNC error signal 1: SYNC error signal generated

Bit	Field	Type	Reset	Description
7: 4	Reserved			Reserved, always read as 0.
3	ESYNCF	r	0x00	Expected SYNC flag This flag is set by hardware when the error frequency counter reaches 0. If the ESYNCIE bit of the CRS_CR register is set, an interrupt will be generated; this bit is cleared by software setting the ESYNCC bit in the CRS_ICR register. 0: No expected SYNC signal 1: Expected SYNC signal generated
2	ERRF	r	0x00	Error flag This flag is set by hardware when a synchronization or tirmming error occurs.This bit is determined by the combination logic of TRIMOVF, SYNCMISS and SYNCERR. If the ERRIE bit in the CRS_CR register is set, an interrupt will be generated. TRI-MOVF, SYNCMISS, and SYNCERR are cleared by software setting the ERRC bit in the CRS_ICR register. 0: No synchronization or tirmming error signal 1: Synchronization or tirmming error signal generated
1	SYNCWARNF	r	0x00	SYNC warning flag This flag is set by hardware when the measured frequency error is greater than or equal to 3 times FELIM but lower than 128 times FELIM. This means that it is necessary to correct the frequency error with two or even more shift positions. If the SYNCWARNIE bit of the CRS_CR register is set, an interrupt will be generated. This bit is cleared by software setting the SYNCWARNC bit in the CRS_ICR register. 0: No SYNC warning signal 1: SYNC warning signal generated
0	SYNCOKF	r	0x00	SYNC event OK flag This flag is set by hardware when the measured frequency error is lower than 3 times FELIM. This means that the trimming is not required or only one shift position enables correcting the frequency error. If the SYNCOKIE bit in the CRS_CR register is set, an interrupt will be generated. This bit is cleared by software setting the SYNCOKC bit in the CRS_ICR register. 0: No SYNC behavior OK signal 1: SYNC behavior OK signal generated

24 Advanced encryption standard hardware accelerator(AES)

AES

AES is only available in devices with AES peripherals.

24.1 AES introduction

The AES hardware accelerator encrypt and decrypt data with the AES algorithm, and is fully compatible to achieve the following standards:

- The advanced encryption standard (AES) accelerator defined by FIPS (FIPS PUB 197, 2001 November 26)

The AES encrypts and decrypts 128-bit blocks using 128-bit or 192-bit or 256-bit keys. It can also perform key expansion. To simplify the operation of the CPU or DMA when processing some data using the same key, the encryption or decryption key is stored in an internal register block. By default, the electronic code book (ECB) is selected. AES supports the cipher block chaining (CBC), counter mode (CTR), ciphertext feedback mode (CFB), and output feedback mode (OFB), as well as DMA transfer of input and output data (requiring 2 DMA channels).

24.2 AES main features

- Encryption/decryption using the AES Rijndael block cipher algorithm
- Compatible with NIST FIPS 197 AES encryption/decryption algorithm
- Internal 256-bit registers storage encryption and decryption keys (8x32-bit register blocks)
- Support for five chaining modes
  - Electronic code book(ECB)
  - Cipher block chaining(CBC)
  - Counter Mode(CTR)
  - Ciphertext feedback mode(CFB)
  - Output feedback mode(OFB)
- Key scheduling
- Key expansion for decryption
- Processing 128-bit data blocks
- Support three key lengths
  - 128bit
  - 192bit
  - 256bit

- 1x32 bit input buffer and 1x32 bit output buffer
- Only support 32-bit data width register access
- Suspend messages if you need to process another message with a higher priority
- Automatic data flow control supports direct memory access (DMA) with 2 channels, one for input data and one for output data

24.3 AES Functional description

The figure below shows a block diagram of the AES accelerator.

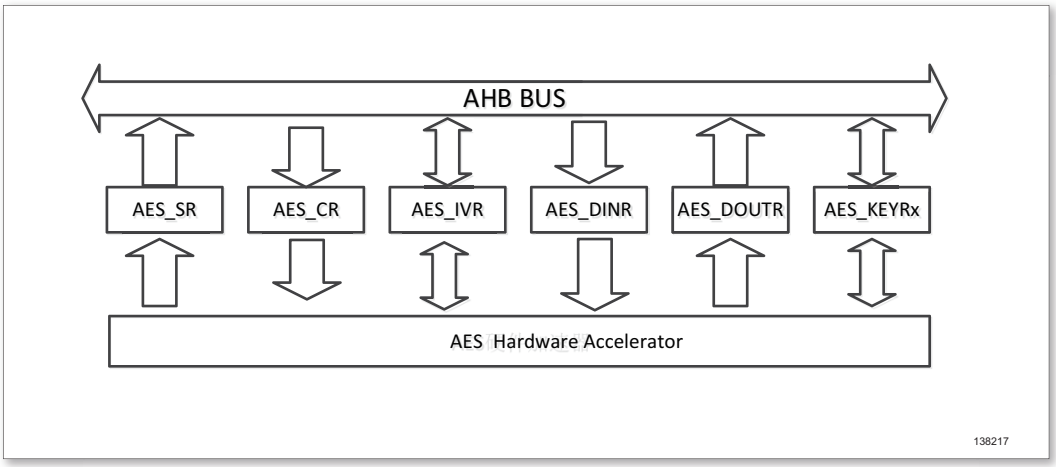

Figure 253. AES Block Diagram

The AES accelerator uses a length-optional key (128-bit, 192-bit and 256-bit), to process 128-bit (4-word) blocks (plaintext), and sets an initialization vector when selecting CBC, CTR, CFB, or OFB chaining mode. It supports 4 operating modes:

- Mode 1: Encryption is achieved with the encryption key stored in the AES_KEYRx register.
- Mode 2: The expanded key is stored inside the AES_KEYRx register at the end of the key extension and is extended before AES is enabled. This mode is independent of the chaining mode selected by AES.
- Mode 3: Decryption is realized through the predefined (pre-computed) decryption key stored in the AES_KEYRx register.
- Mode 4: Key expansion + decryption are achieved with an encryption key stored in AES_KEYRx (not used when AES is configured in counter mode).

The operating mode can be selected by programming the MODE1:0 bits of the AES_CR register. Mode selection can only be modified if AES is disabled (EN = 0 in the AES_CR register), and the key register (AES_KEYRx) must be stored before AES is enabled.

To select one of the ECB, CBC, CTR, CFB or OFB modes for the encryption or decryption, CHMOD2:0 and AES_IVR in the AES_CR register must be written when AES is disabled (bit EN = 0 in the AES_CR register) (only applicable to CBC, CTR, CFB or OFB chaining mode).

Once being enabled (EN = 1), AES is in the input phase, waiting for the software to write the input data word to AES_DINR (4 words) for mode 1, 3 or 4; the data shall be a plain

text message or an encrypted message. A latent period is automatically inserted between two consecutive write operations to the AES_DINR register, so as to send the key that interacts with the data to the AES processing module.

For Mode 2, the key is expanded immediately after the EN in the AES_CR register is set. It requires that the AES_KEYRx register has been loaded with an encrypted KEY before AES is enabled. At the end of key expansion processing (setting CCF = 1), the extended key in the AES_KEYRx register is available and AES is disabled by hardware. In this mode, the AES_KEYRx register cannot be read when AES is enabled and the hardware sets the CCF flag to 1.

After the calculation phase, the status flag CCF (Computation Complete Flag) in the AES_SR register is set; an interrupt may be generated if CCFIE is 1 in the AES_SR register. The software can then read back the data from the AES_DOUTR register (for Modes 1, 3, 4) or from the AES_KEYRx register (if Mode 2 is selected).

When DMAOUTEN is 1 in the AES_CR register, the flag CCF is meaningless X since the read AES_DOUTR register is automatically managed by the DMA without any software operation at the end of calculation phase.

The operation ends with an output phase during which the software continuously reads four output data words from the AES_DOUTR register in Modes 1, 3 or 4. In Mode 2 (key expansion mode), data is automatically stored in the AES_KEYRx register and AES is disabled by hardware. Then, before enabling AES, the software can select Mode 3 (decryption mode), to enable decryption using the expanded key.

During the input and output phases, software must continuously read or write data bytes (except Mode 2), but AES allows for any delay between each read or write operation (for example, if another interrupt is maintained at this time).

The RDERR and WRERR flags in the AES_SR register are set when an unexpected read or write is detected. An interrupt may be generated if the ERRIE bit is set in the AES_CR register. After error detection, AES will not abort but continue processing normally.

A general-purpose DMA can be used to write the input word and read the output word (refer to Figure 254 and Figure 255).

AES can be reinitialized at any time by resetting the EN bit in the AES_CR register. You can then restart AES from the beginning by setting EN= 1 and wait for the first input data byte to be written (unless in Mode 2, once the EN bit is set, the key expansion begins with the value stored in the AES_KEYRx register).

24.4 Encryption and key expansion

The AES_KEYRx register is used to store the encryption or decryption key. These four (6x192-bit keys, 8x256-bit keys) registers are organized in little endian: the AES_KEYR0 register must be loaded with the 32-bit LSB of the key. Therefore, AES_KEYR3 (AES_KEYR5, AES_KEYR7) must load a 32-bit MSB with a 128-bit key (32-bit MSB of 192-bit keys, and 32-bit MSB of 256-bit keys).

NOTE:

1. When the key length is 128 bit, 192 bit or 256 bit, AES_KEYR0 to AES_KEYR3 will be used.
2. When the key length is 192 bit or 256 bit, AES_KEYR4 and AES_KEYR5 are also used.
3. AES_KEYR6 and AES_KEYR7 are only used if the key length is 256 bit.

When AES is disabled (EN = 0 in the AES_CR register), the encrypted or decrypted key must be stored in these registers, with the fixed storage order.

In Mode 2 (key expansion), AES_KEYRx needs to load the encryption key. Then, it enables AES. At the end of the calculation phase, the expanded key is automatically stored in the AES_KEYRx register, overwriting the previous encryption key. AES is disabled by hardware when an expanded key is available. If the software needs to switch AES to Mode 3 (decryption mode), and if the contents of the AES_KEYRx register correspond to the expanded key (previously calculated in Mode 2), the AES_KEYRx register need not to be written.

In Mode 4 (key expansion + decryption), the AES_KEYRx register contains only the encryption key. The expanded key is internally calculated without any write operation to these registers.

24.5 AES chaining algorithm

The AES hardware supports five algorithms that can be selected by setting CHMOD 2: 0 bits in the AES_CR register when AES is disabled (bit EN = 0):

- Electronic code book(ECB)
- Cipher block chaining(CBC)
- Counter mode(CTR)
- Ciphertext feedback mode(CFB)
- Output feedback mode(OFB)

24.5.1 Electronic code book(ECB)

This is the default mode, which does not use the AES_IVR register, without chaining operation. Messages that need to be encrypted are divided into blocks according to the block size (128 bits) of the processed data, and each block is independently encrypted or decrypted.

Figure 254 and Figure 255 illustrate the principles of the electronic codebook algorithm for encryption and decryption respectively.

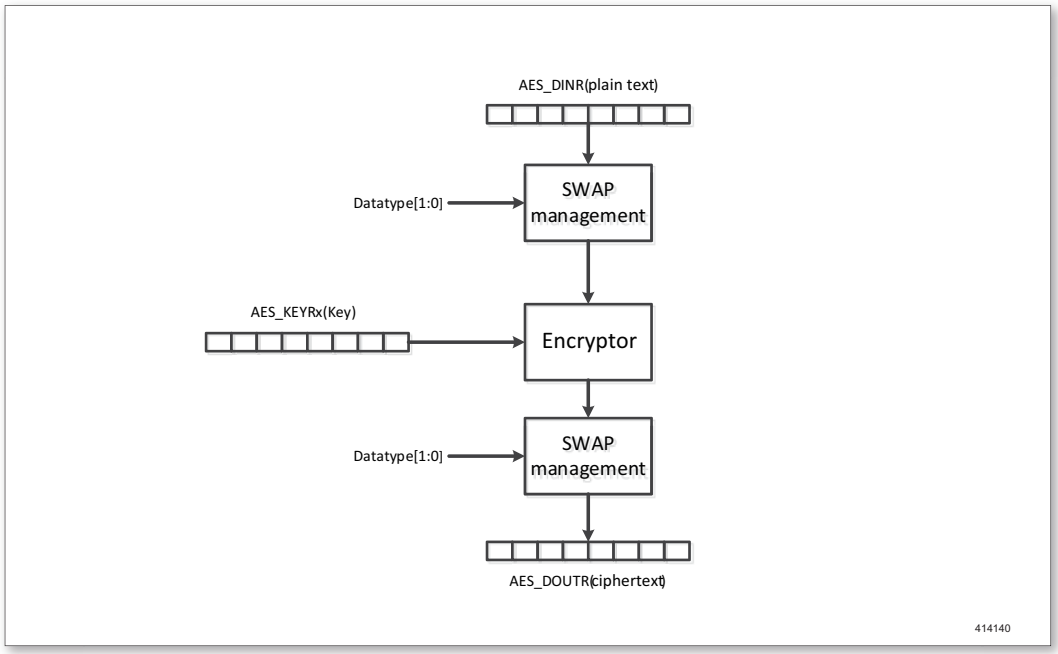

Figure 254. ECB Encryption Mode

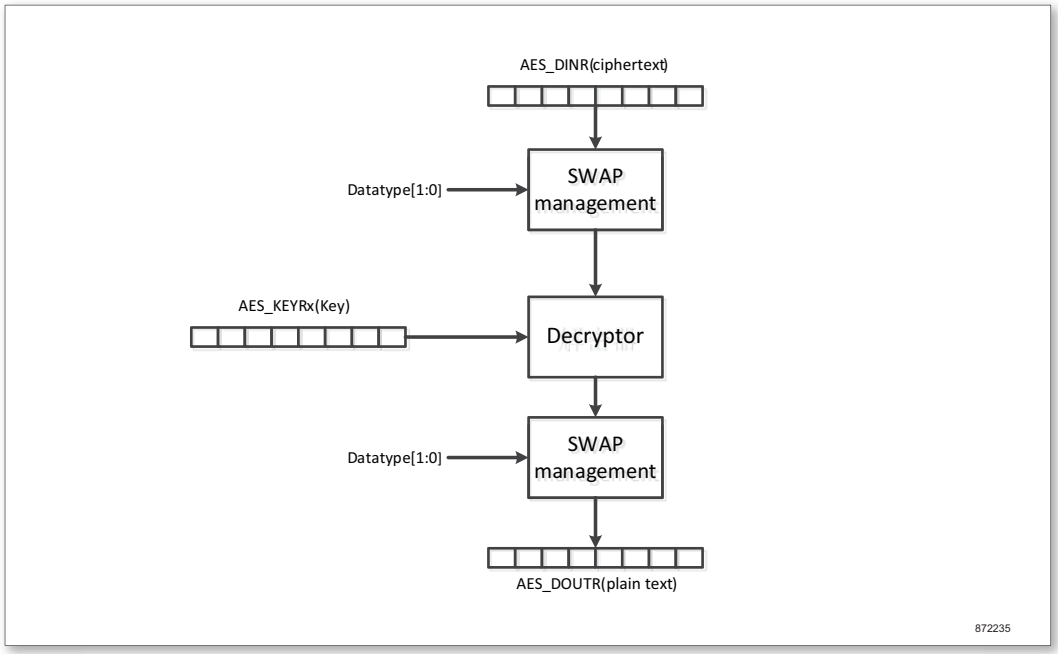

Figure 255. ECB Decryption Mode

24.5.2 Cipher block chaining(CBC)

In the cipher block chaining (CBC) mode, each plaintext block is XORed with the previous ciphertext block prior to encryption. In order to make each message unique, an initialization vector (AES_IVRx) is used when the first block is processed.

In the encryption mode, the initialization vector is XORed after data exchange management; in the decryption mode, the initialization vector is XORed before data exchange management (refer to Figure 256 and Figure 257).

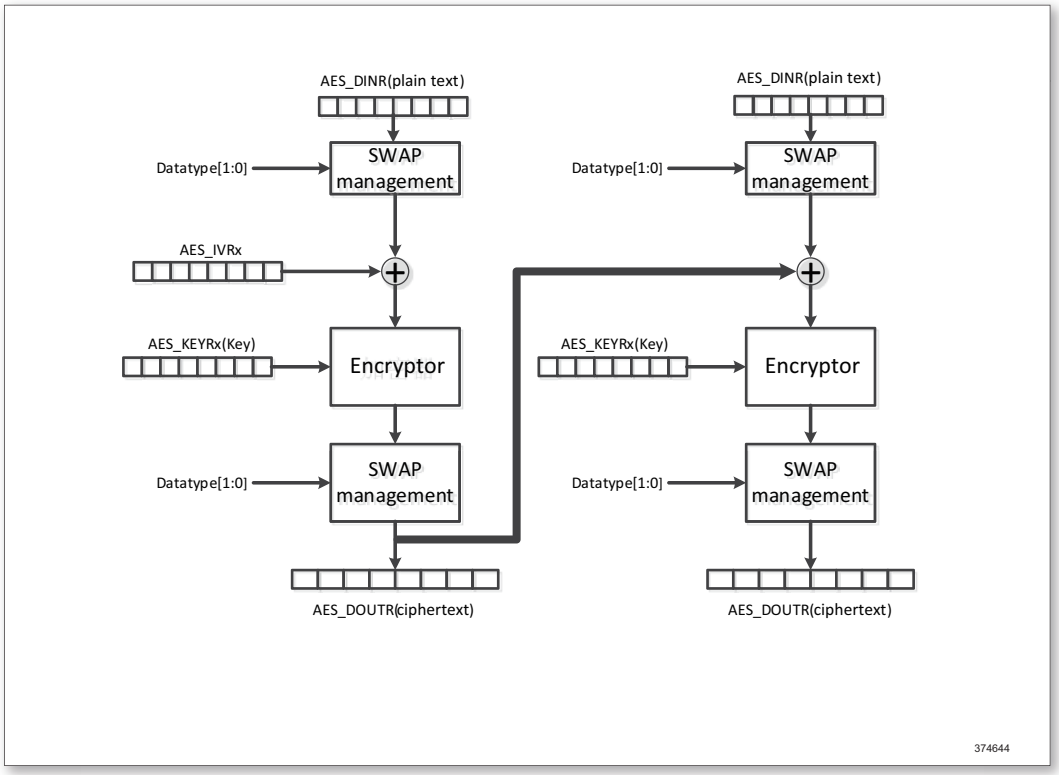

Figure 256. Encryption in CBC Mode

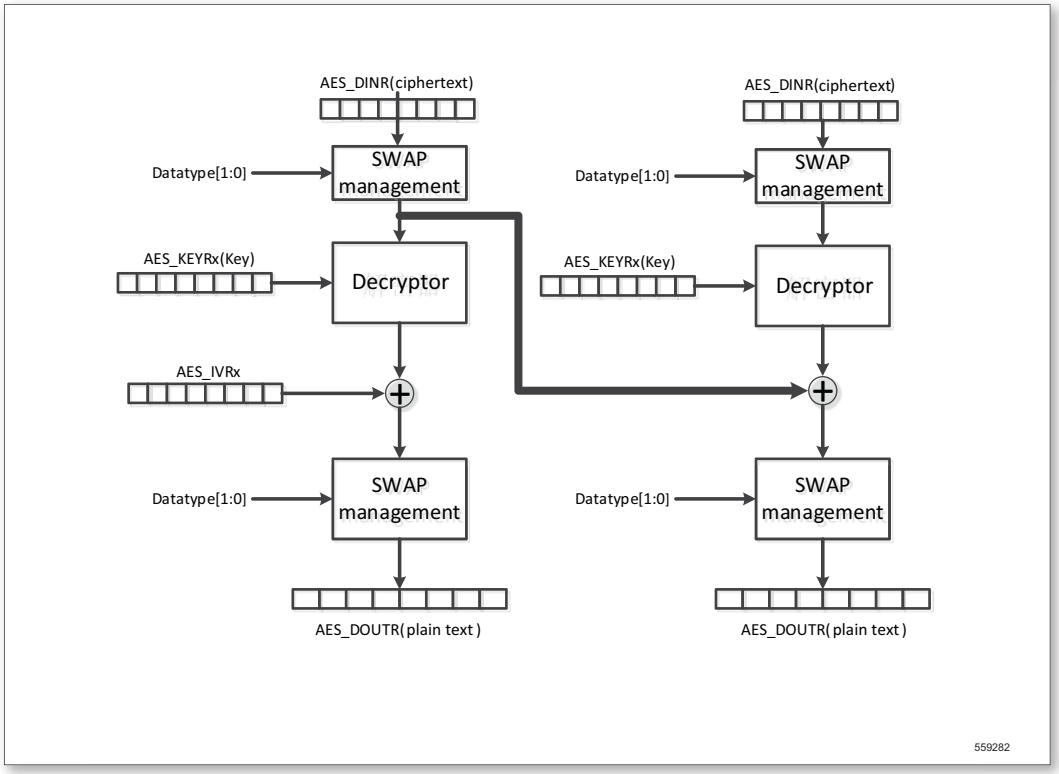

Figure 257. Decryption in CBC Mode

Note: When AES is enabled, the return value of AES_IVR read is 0x00000000.

Suspend mode of a given message

If you need to process another message with a higher priority, you can suspend the message. After the transmission of the highest priority message, the suspended message can be resumed in the encryption or decryption mode. This feature is only available when the data transfer is completed by the CPU accessing the AES_DOUTR and AES_DINR registers. It is recommended not to use the DMA controller when managing data transfers.

For proper operation, the message must be suspended at the end of processing block (after reading AES_DOUTR register in the fourth time and before the write access of next AES_DINR corresponding to the input of the next block to be processed).

To write EN = 0 in the AES_CR register, AES shall be disabled. The software must read AES_IVRx, which contains the most recent value for chaining XOR operation before the message interrupt. The value must be written to AES_IVRx register when the interrupt message has been resumed (AES disabled) for reuse.

Note: This will not interrupt the chaining operation, and the next 128-bit block is sent once AES is enabled again, to resume message processing.

Note: This behavior is valid regardless of the AES configuration (encryption or decryption mode).

Figure 258 shows an example of sending Message 2 shorter than Message 1 and with higher priority by suspending Message 1. At the end of 128-bit block processing, AES is disabled. When the message is resumed, the AES_IVR register is read back, to store the value to be retrieved later, so as not to interrupt the chaining operation. AES is then configured to send Message 2 and enable it to start processing. After Message 2 processing, AES must be disabled again and the AES_IVRx register previously storing the value must be loaded when Message 1 is interrupted. Finally, once AES is enabled to recover Message 1, the software must restart from the input value corresponding to Data block 4.

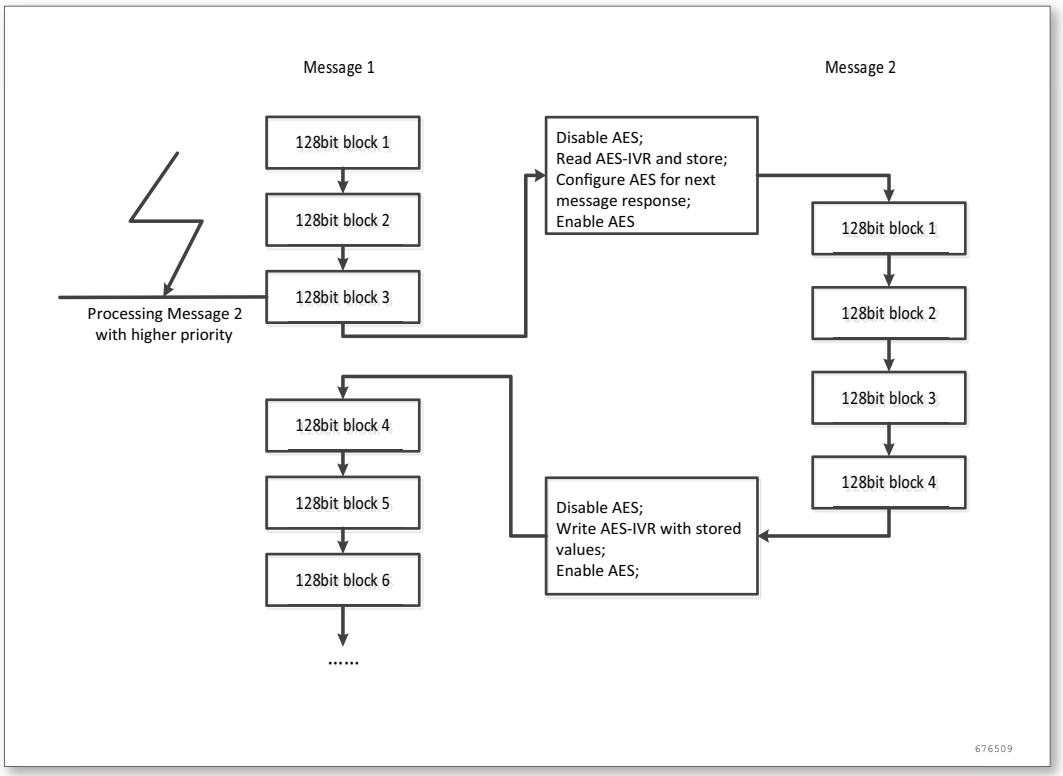

Figure 258. Management Diagram in Suspend Mode

24.5.3 Counter Mode (CTR)

In counter mode, in addition to random values for XOR operations using ciphertext or plain text, a 32-bit counter is used (see Figure 259 and Figure 260).

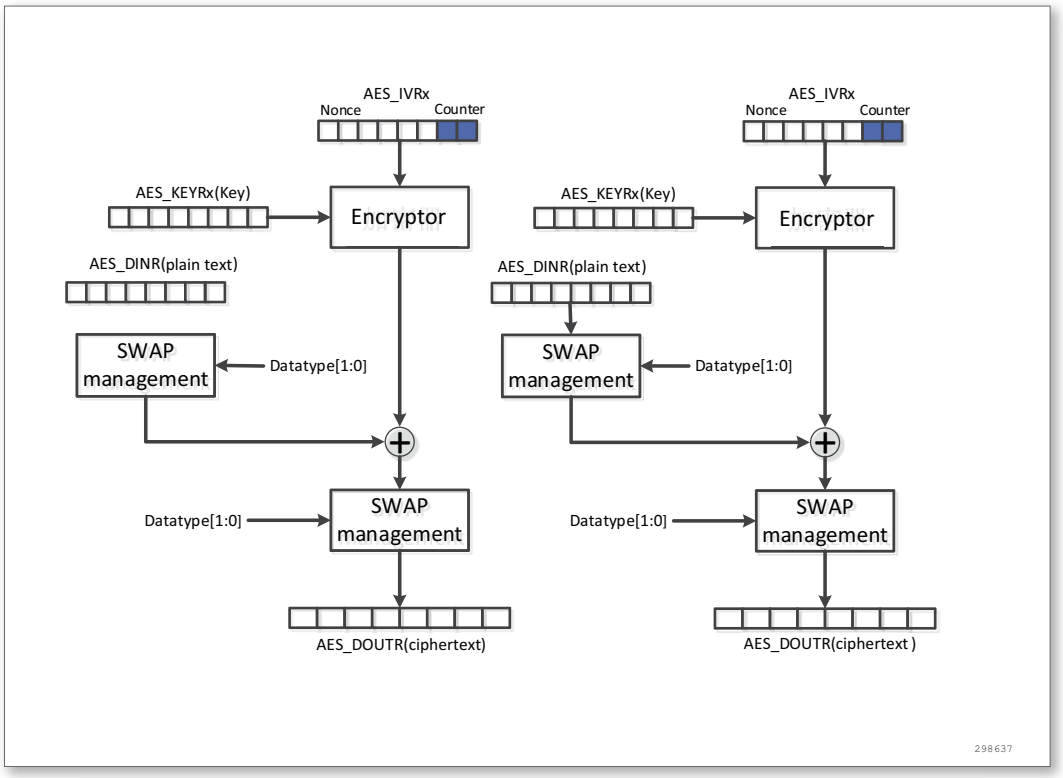

Figure 259. Encryption in CTR Mode

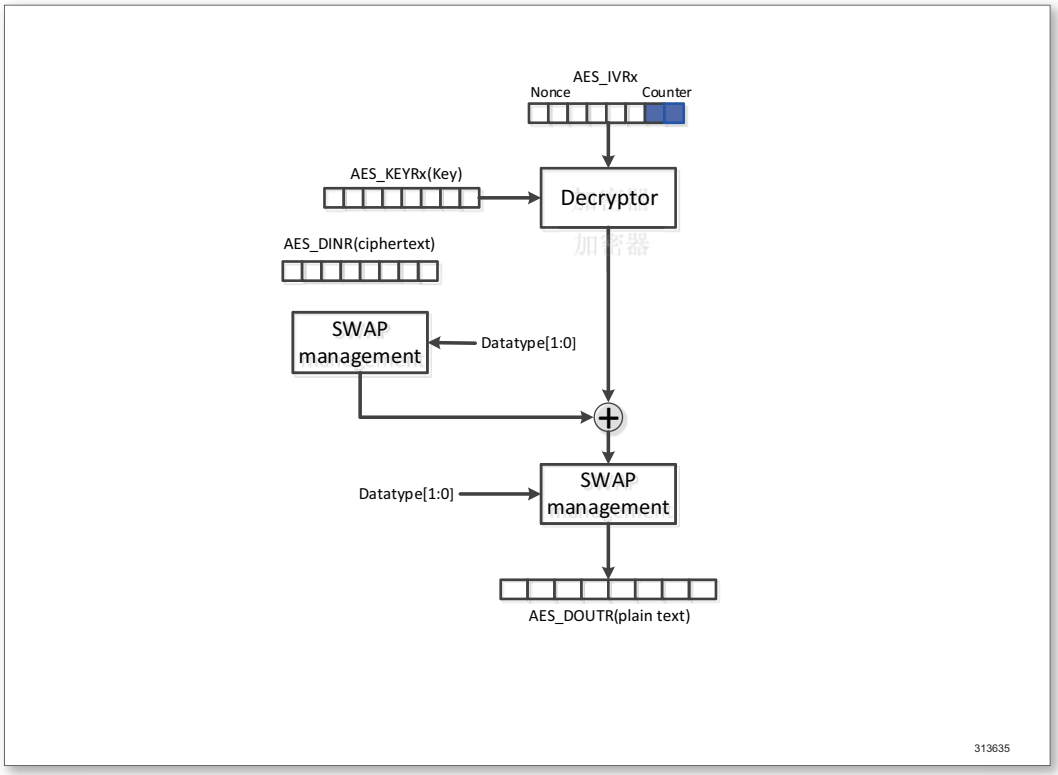

Figure 260. Decryption in CTR Mode

Random values and 32-bit counters are accessed through the AES_IVRx register and organized, as shown below:

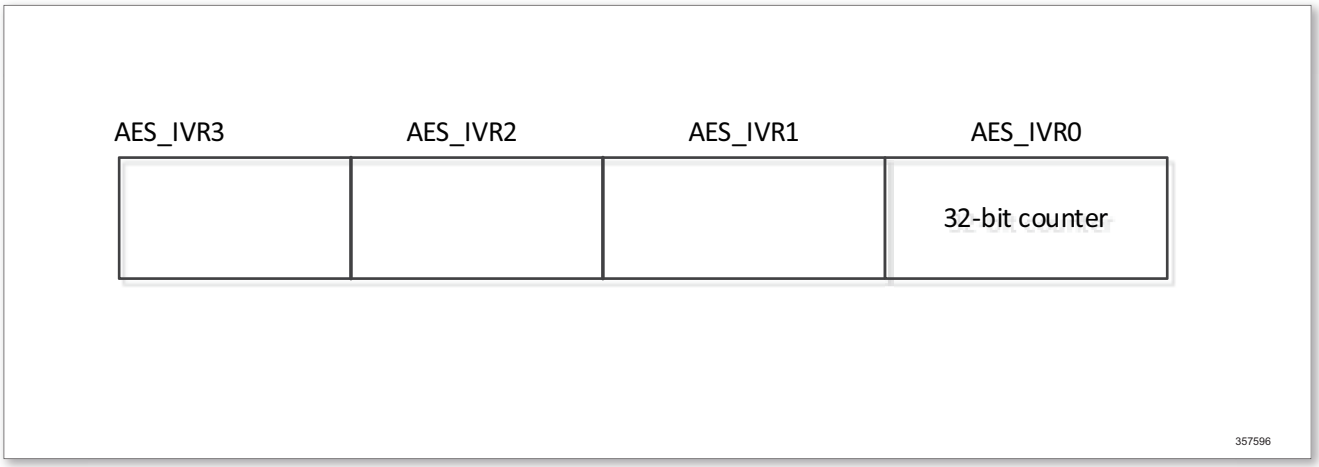

Figure 261. 32-bit Counter+Random Value Organization

In counter mode, the counter is incremented from the initialization value of each block to be processed, to guarantee a unique sequence that will not repeat for a long time. It is a 32-bit counter, which means that the random number message remains initialized when AES is disabled. The counter is represented by only the 32-bit LSB of the 128-bit initialization vector register. In contrast to CBC mode (using AES_IVRx register once when processing the first data block), the AES_IVRx register is used to process each data block.

In counter mode, key expansion + decryption mode is not applicable.

Note:

1. The AES_IVRx register is written only when AES (EN = 0) is disabled, to ensure good AES behavior.
2. Read it when AES is enabled, with the return value of 0x00000000
3. Read it when AES is disabled, to return the latest counter value (used to manage suspend mode).

Key expansion + decryption takes no effect in CTR mode. Therefore, it is prohibited to force MODE1:0 = 11 in the AES_CR register and such an attempt will force MODE 1:0 = 10 (corresponding to decryption in CTR mode). The ciphertext is decrypted by using the encipher of AES, as shown in the figure (Figure 260).

Suspend mode in CTR mode

Similar to CBC mode, you can interrupt messages, send those with higher priority, and recover interrupted messages. Refer to Figure 258 and section 24.5.2 for more details on the Suspend Mode features.

24.5.4 Ciphertext feedback mode (CFB)

The ciphertext feedback mode is similar to CBC. In this mode, the block cipher can be changed into a self-synchronizing stream cipher; the working process is also very similar, and the CFB decryption process is almost the reverse CBC encryption process. The encryption process in CFB mode can be decomposed into the following steps:

- XOR the plaintext with the encrypted result of IV to obtain the ciphertext, as shown in Figure 262
- Encrypt the initialization vector by using cipher (IV)

The decryption process in CFB mode is decomposed into

- Encrypt the initialization vector by using cipher (IV)
- XOR the ciphertext with the encrypted result of IV to obtain the plaintext, as shown in Figure 263

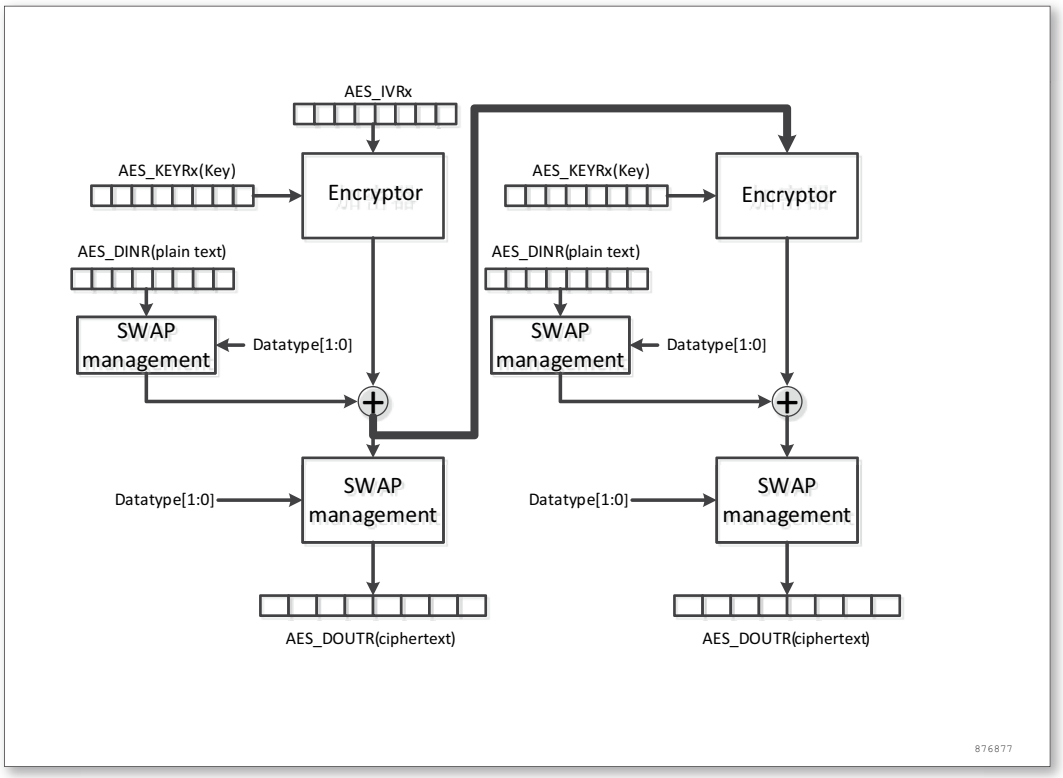

Figure 262. Encryption in CFB Ciphertext Feedback Mode

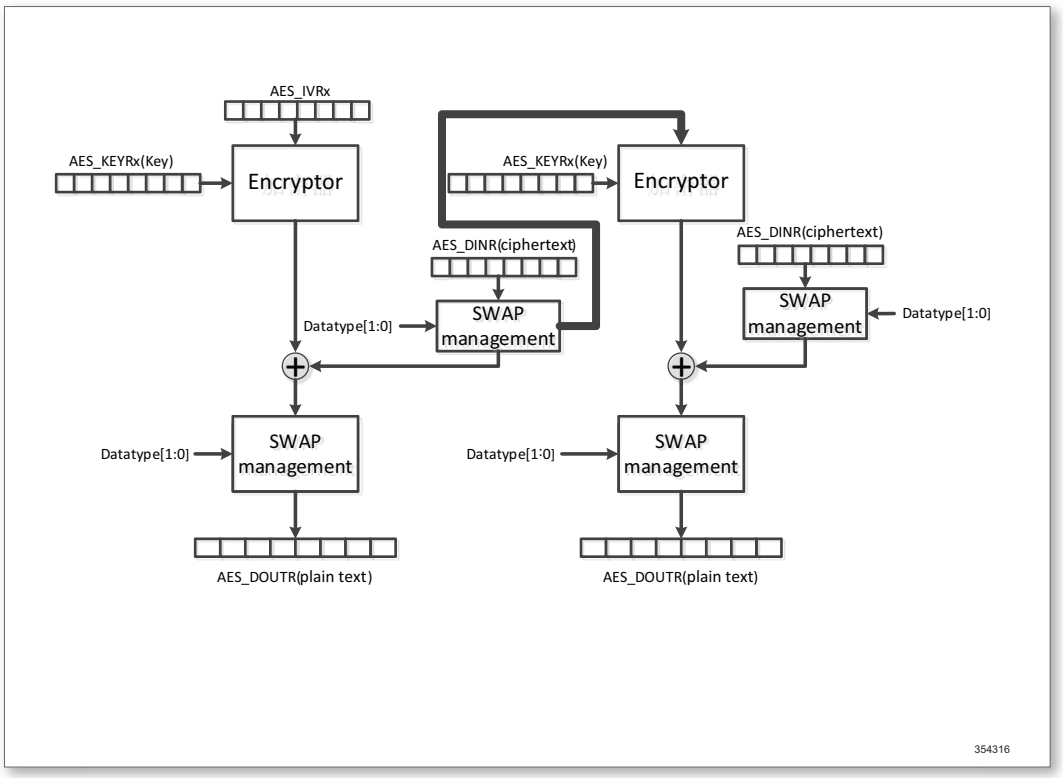

Figure 263. Decryption in CFB Ciphertext Feedback Mode

Suspend mode in CFB mode

Similar to CBC mode, you can interrupt messages, send those with higher priority, and recover interrupted messages. Refer to Figure 258 and section 24.5.2 for more details on

the Suspend Mode features.

24.5.5 Output feedback mode (OFB)

During OFB encryption, the cipher is used to generate the key stream, and then the key stream is XORed with the plaintext stream, to obtain the ciphertext stream. In the decryption process, the key stream is generated by using the cipher, and then the key stream is XORed with the ciphertext stream, to generate the plaintext stream. The operation flow of encryption is the same as that of the decryption.

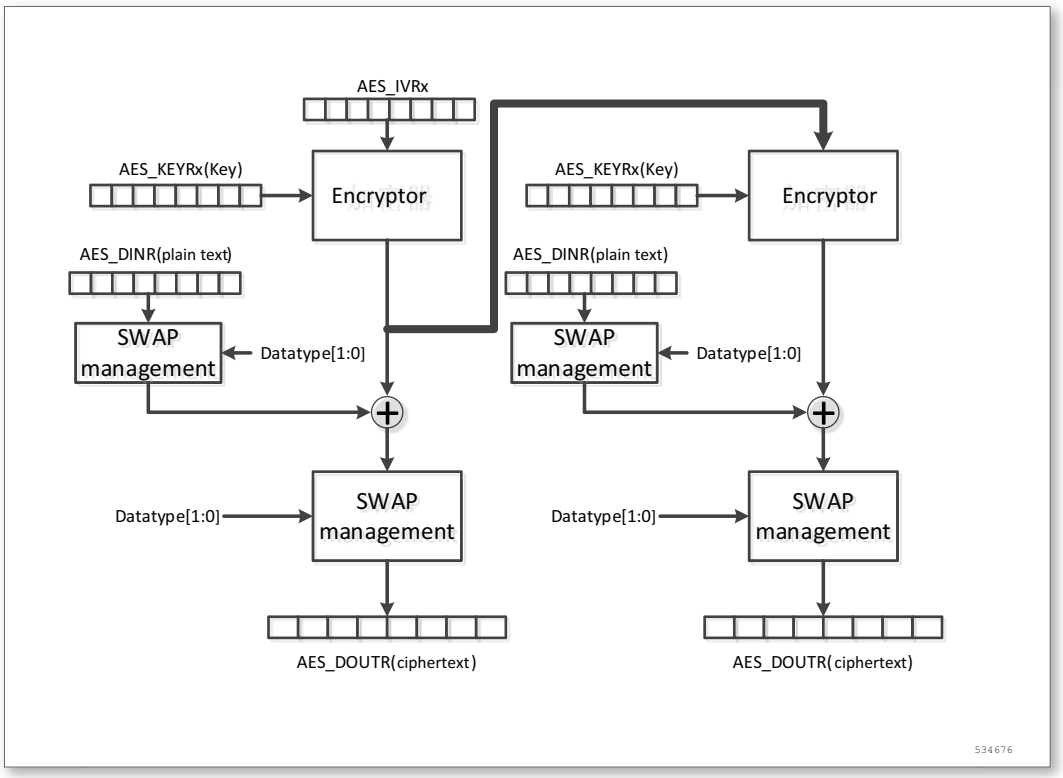

Figure 264. Encryption in OFB Ciphertext Feedback Mode

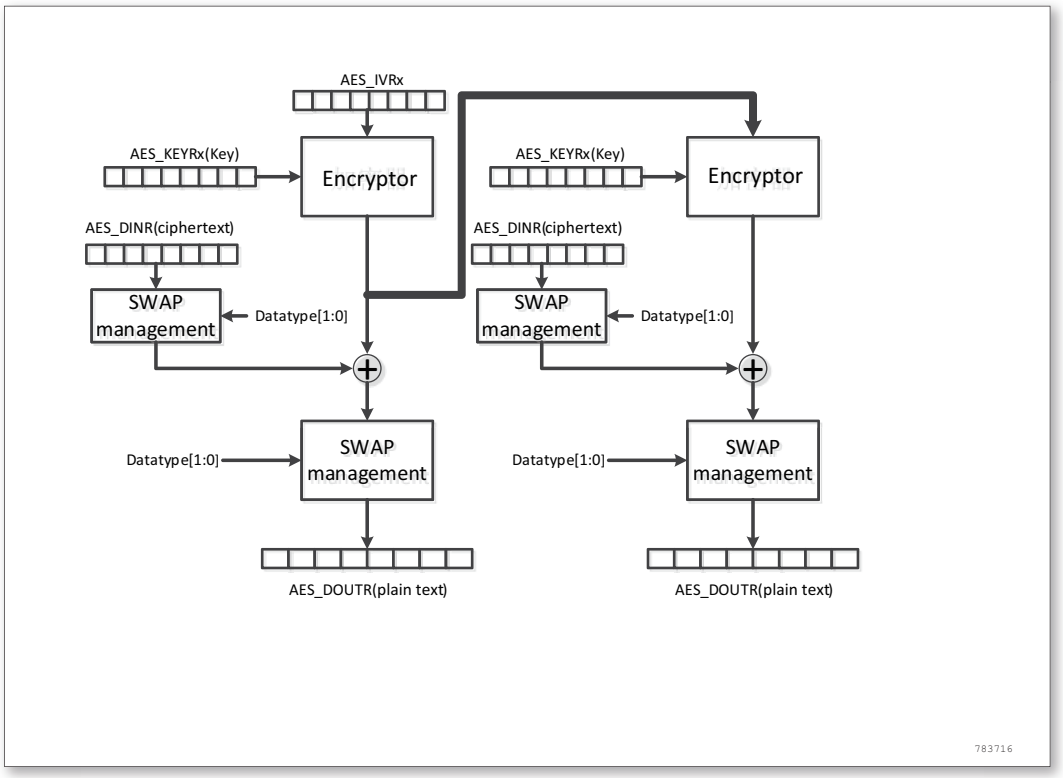

Figure 265. Decryption in OFB Ciphertext Feedback Mode

Suspend mode in OFB mode

Similar to CBC mode, you can interrupt messages, send those with higher priority, and recover interrupted messages. Refer to Figure 258 and section 24.5.2 for more details on the Suspend Mode features. Note: The encipher, instead of decryptor, is used for decryption in CFB, OFB, and CTR modes.

24.6 Data type

32-bit (byte) data is input to the AES processor at a time by writing data to the AES_DINR register; AES is used to process 128-bit data blocks; the AES_DINR or AES_DOUTR registers must be read or written four times, to process a 128-bit data block with the most significant bit.

The system memory organization is little-endian: no matter which data type (bit, byte, 16-bit halfword, 32-bit word) is used, the lower valid data occupies the lowest address. Therefore, before AES processing, the data execution bit of AES_DINR must be written from the systerm memory through byte or halfword swap operation, and the same exchange, from AES_DOUTR register to the system memory, must be executed for the AES data to be read, depending on the type of data to be encrypted or decrypted.

The DATATYPE bits in the AES_CR register support different swap modes, which are applied to the AES_DINR register before the data is sent to the AES module and applied to the data output from the AES module on the AES_DOUTR register (refer to Figure 262).

Note: The swap operation only involves the AES_DOUTR and AES_DINR registers. The AES_K-

EYRx and AES_IVRx registers are not sensitive to the selected swap mode, and they have a fixed little-endian configuration (Refer to subsec 24.4 and subsec 24.12).

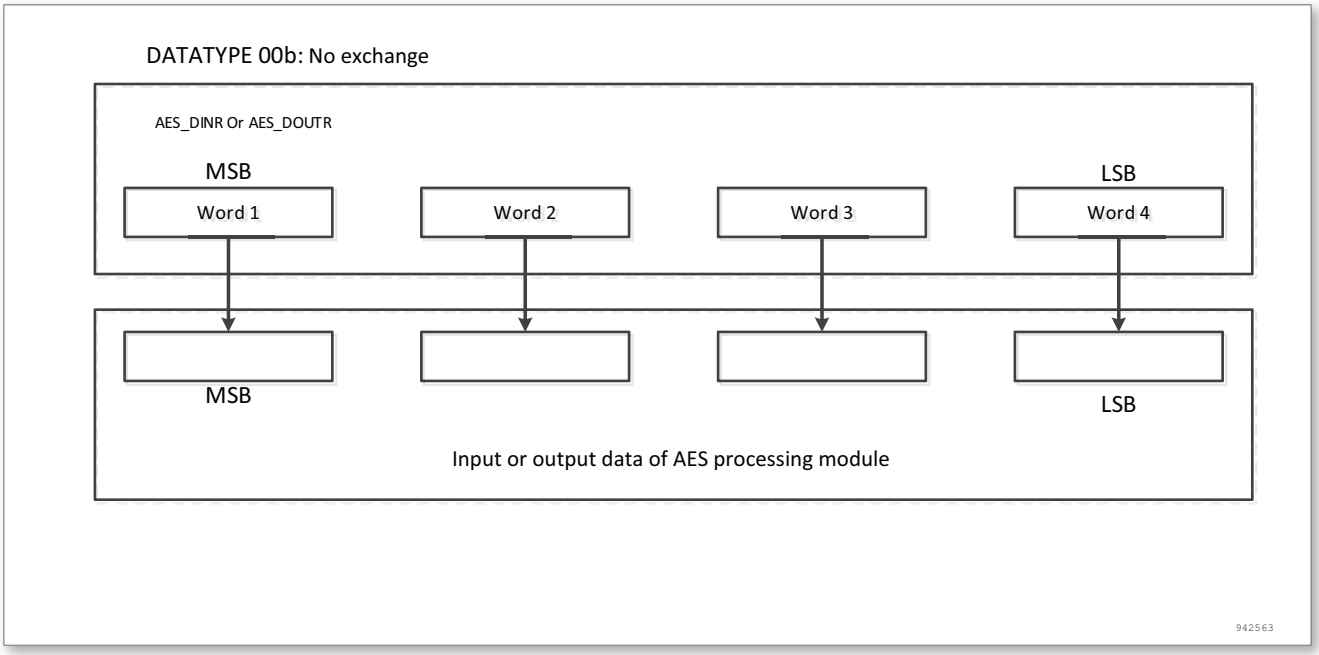

Figure 266. Exchange Mode: No Exchange

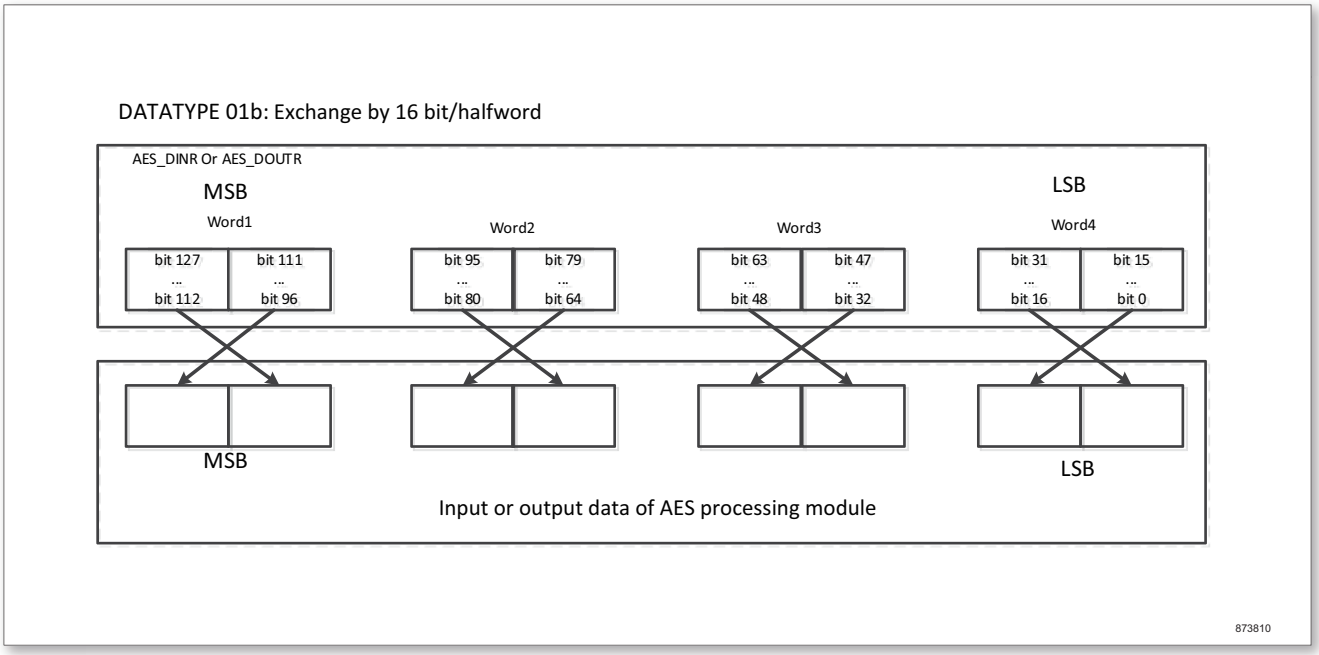

Figure 267. Swap Mode: Exchange by 16 bit/halfword

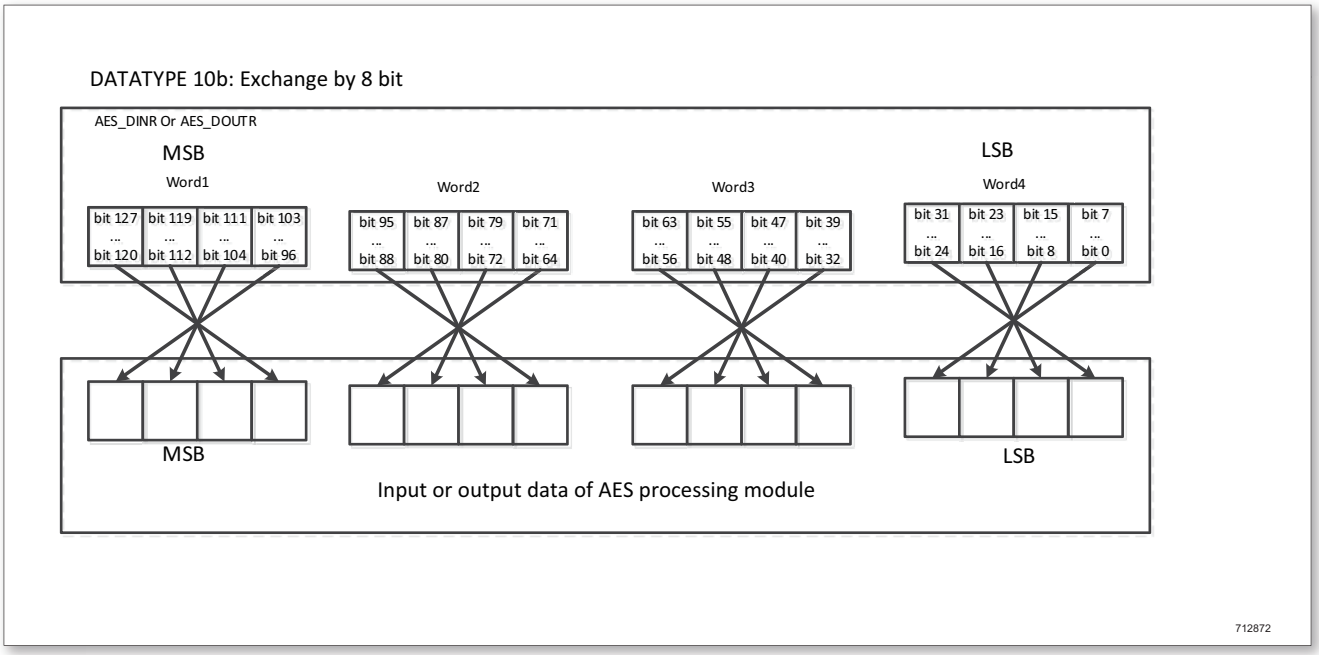

Figure 268. Swap Mode: Exchange by 8 bit

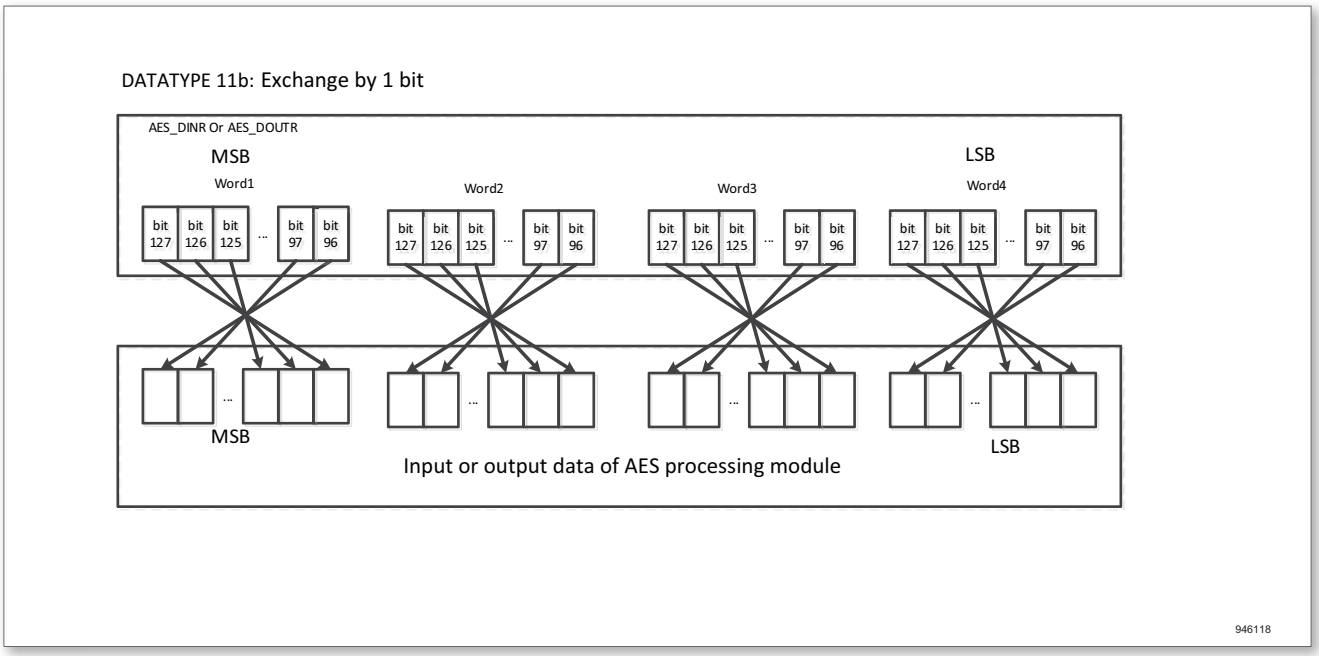

Figure 269. Swap Mode: Exchange by 1 bit

24.7 Operating mode

24.7.1 Mode 1: encryption

1. Disable AES by resetting EN (EN=0) bit in the AES_CR register.
2. Configure Mode 1 by programming MODE2:0=00 in the AES_CR register, and select the specific chaining mode by programming CHMOD2:0 bits.
3. Configure the KSIZE bit in the AES_CR register to select the key length of 128 bit or 192 bit and 256 bit.
4. After selecting CTR, CBC, CFB, or OFB mode, write AES_KEYRx register (128-bit,

192-bit or 256-bit encryption key). In ECB mode, do not use the AES_IVRx register.

5. Enable AES by setting the EN bit in the AES_CR register to ’1’.
6. Write the AES_DINR register 4 times, to enter plain text (MSB first), as shown in Figure 270.
7. Wait until the CCF flag in the AES_SR register is set.
8. Read the AES_DOUTR register 4 times to fetch the ciphertext (MSB first), as shown in Figure 270.
9. Repeat Steps 6, 7, and 8, to process all data blocks with the same encryption key.

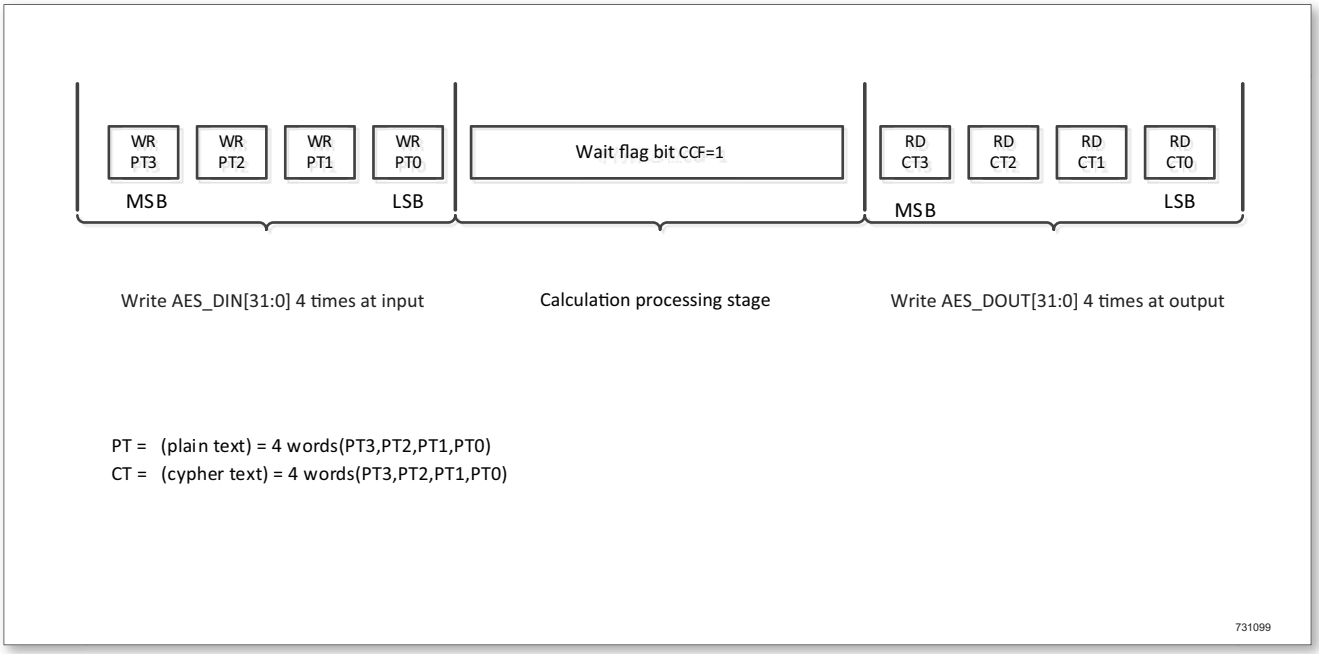

Figure 270. Mode 1: Encryption

24.7.2 Mode 2: key expansion

1. Disable AES by resetting the EN bit in the AES_CR register.
2. Configure Mode 2 by setting MODE 1:0 = 01 in the AES_CR register. Note: In this case, the CHMOD 2:0 bit does not need to be configured because the key expansion mode is independent of the selected chaining algorithm.
3. Configure the KSIZE bit in the AES_CR register, to select the key length of 128 bit, 192 bit or 256 bit.
4. Write to the AES_KEYRx register by using the encryption key, to get the expanded key; writing to AES_IVRx is invalid.
5. Enable AES by setting the EN bit in the AES_CR register to ’1’.
6. Wait until the CCF flag in the AES_SR register is set.
7. The expanded key is automatically stored in the AES_KEYRx register. If necessary, the AES_KEYRx register is read, to fetch the decryption key. AES is disabled by hardware. To restart the expanded key calculation, repeat Steps 3, 4, 5, and 6.

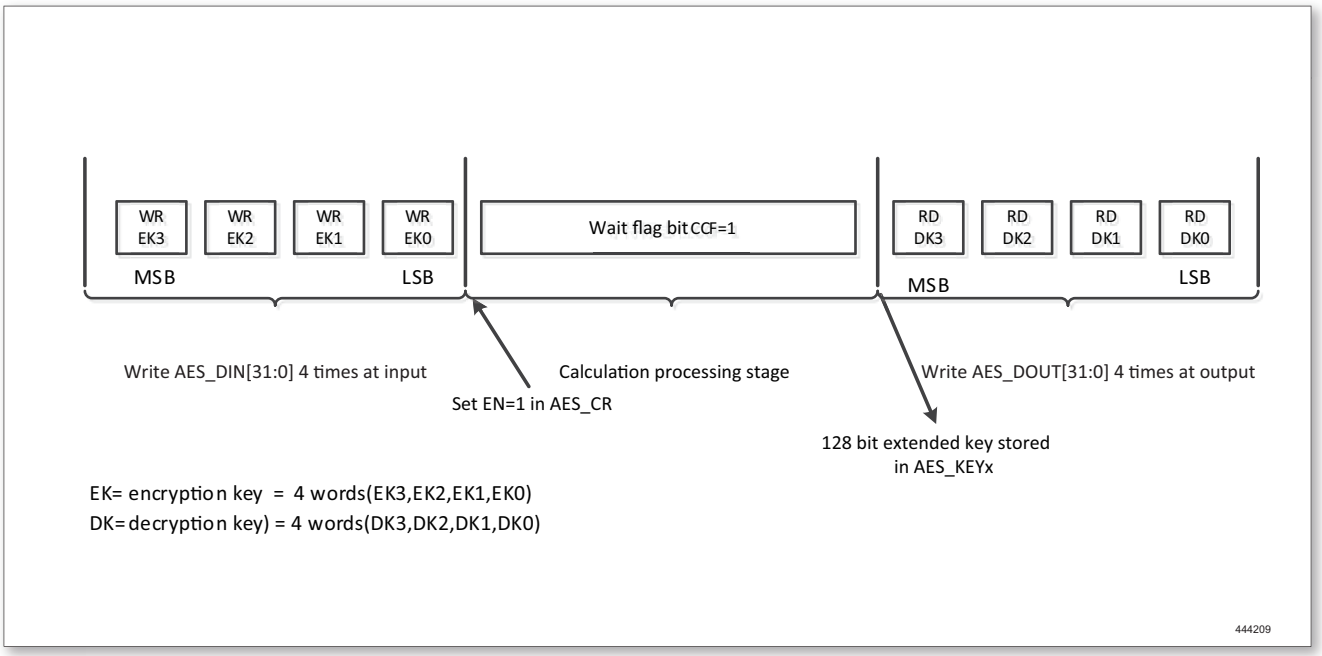

Figure 271. Mode 2: Key Expansion

24.7.3 Mode 3: Decryption

1. Disable the AES by resetting the EN bit in the AES_CR register.
2. Configure Mode 3 by programming MODE 1:0 = 10 in the AES_CR register and select the specific chaining mode by programming CHMOD 2:0 bits.
3. Configure the KSIZE bit in the AES_CR register to select the key length of 128 bit, 192 bit or 256 bit.
4. Write to the AES_KEYRx register by using the decryption key (this step can be ignored if the expanded key has been stored in the AES_KEYRx register in Mode 2: key expansion). If the CTR or CBC mode is selected, the data is written to the AES_IVRx register. In ECB mode, the AES_IVRx register is not used.
5. EnableAES by setting the EN bit in the AES_CR register to ’1’.
6. Write the AES_DINR register 4 times, to input the ciphertext (MSB first), as shown in Figure 272.
7. Wait until the CCF flag in the AES_SR register is set.
8. Read the AES_DOUTR register 4 times to fetch plain text (MSB first), as shown in Figure 272.
9. Repeat Steps 6,7,8 to process all data blocks with the same expanded key stored in the AES_KEYRx register.

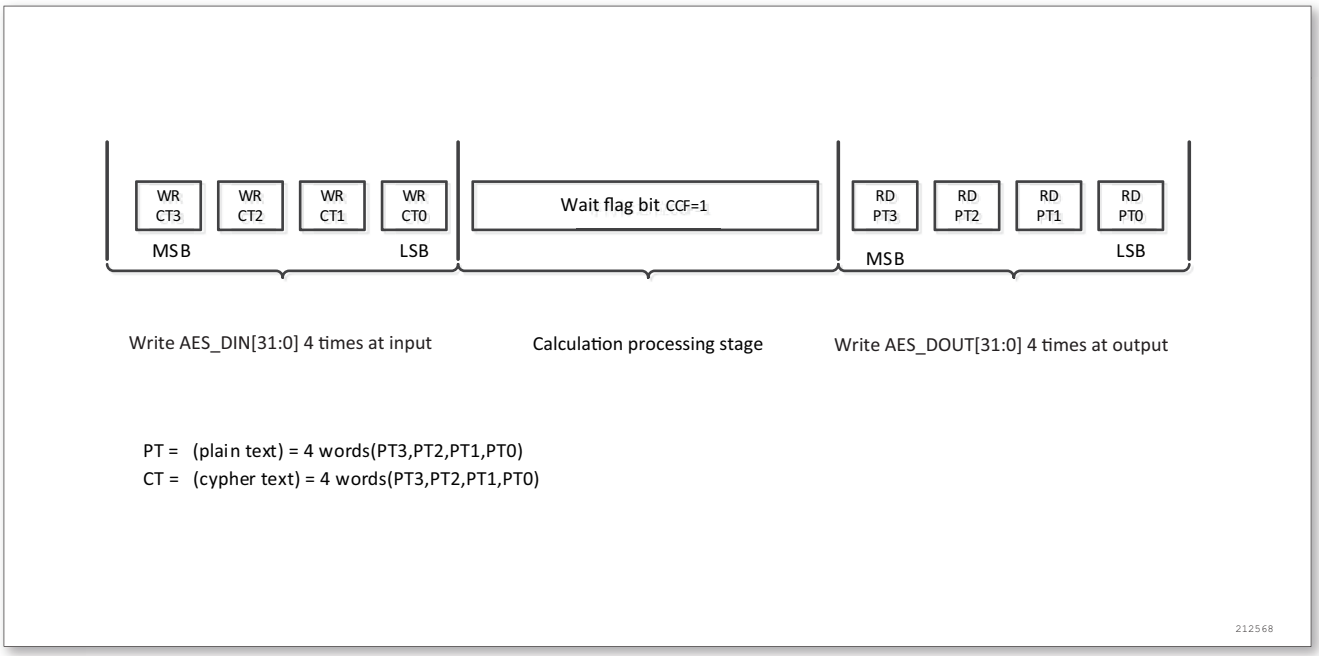

Figure 272. Mode 3: Decryption

24.7.4 Mode 4: key expansion and decryption

1. Disable AES by resetting the EN bit in the AES_CR register.
2. Configure Mode 4 by setting MODE 1:0 = 11 in the AES_CR register. This operating mode is disabled when AES is configured in CTR mode. If the software writes MODE 1:0 = 11 and CHMOD 2:0 = 010, it will be forced into the CTR decryption mode.
3. Configure the KSIZE bit in the AES_CR register, to select the key length of 128 bit, 192 bit or 256 bit.
4. Write to the AES_KEYRx register with the encryption key. If you select CBC, CFB or OFB mode, write to the AES_IVRx register.
5. Enable AES by setting the EN bit in the AES_CR register to ’1’.
6. Write the AES_DINR register 4 times, to enter plain text (MSB first), as shown in Figure 273.
7. Wait until the CCF flag in the AES_SR register is set.
8. Read the AES_DOUTR register 4 times to fetch the ciphertext (MSB first), as shown in Figure 273.
9. Repeat Steps 6, 7, and 8, to process all blocks with the same encryption key.

Note: The AES_KEYRx register contains the encryption key in all processing stages, and the expanded key is not stored in these registers. The expanded key starting with the encryption key is stored in AES, and a copy needed not to be stored in the AES_KEYRx register.

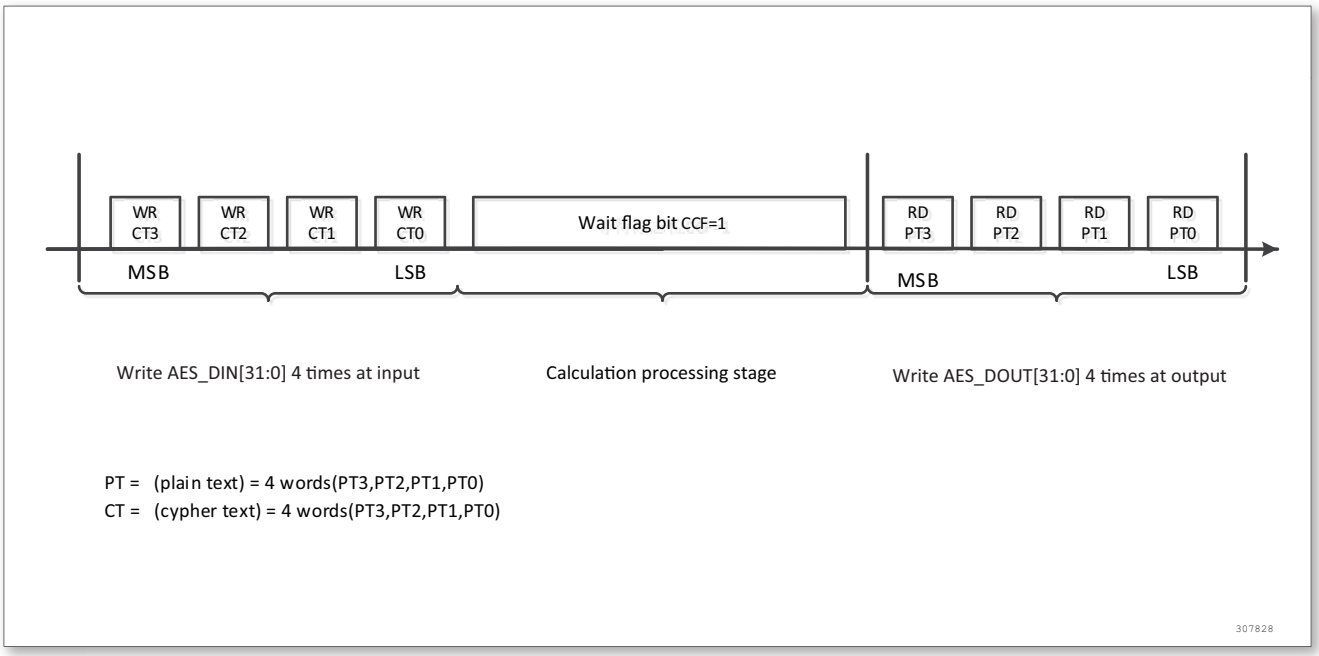

Figure 273. Mode 4: Key Expansion and Decryption

24.8 AES DMA interface

The AES accelerator provides an interface connected to the DMA controller. The DMA must be configured as a transfer word (32 bit).

AES can be associated with two different DMA request channels:

- Input DMA request channel: When the DMAINEN bit is set in the AES_CR register, AES issues a DMA request (AES_IN) at the INPUT stage when a word needs to be written to the AES_DINR register each time. The DMA channel must be configured in memory-to-peripheral mode by using a 32-bit data.
- Output DMA request channel: When the DMAOUTEN bit is enabled, AES issues a DMA request (AES_OUT) in the OUTPUT stage when a word needs to be read from the AES_DOUTR register each time. The DMA channel must be configured in peripheral-to-memory mode, with a data size equal to 32 bits.

Four DMA requests are applied for each stage, which are depicted in Figure 274 and Figure 275.

A DMA request is generated until AES is disabled. Therefore, after processing a 128-bit block after the data output stage, AES will automatically switch to the new data input stage (if any) of the next block.

Note:

1. In Mode 2 (key derivation), the AES_KEYRx register can be accessed by the software of the CPU, but there is no DMA channel available for this purpose. Therefore, in this mode, the DMAINEN bit and the DMAOUTEN bit in the AES_CR register have no effect.
2. When DMAOUTEN is set to 1, the software needs not to read the data, and the CCF flag is invalid. If the application needs to disable AES, to cancel DMA management and use CPU access at the data input or output stage, this bit may remain high and must be cleared by

software.

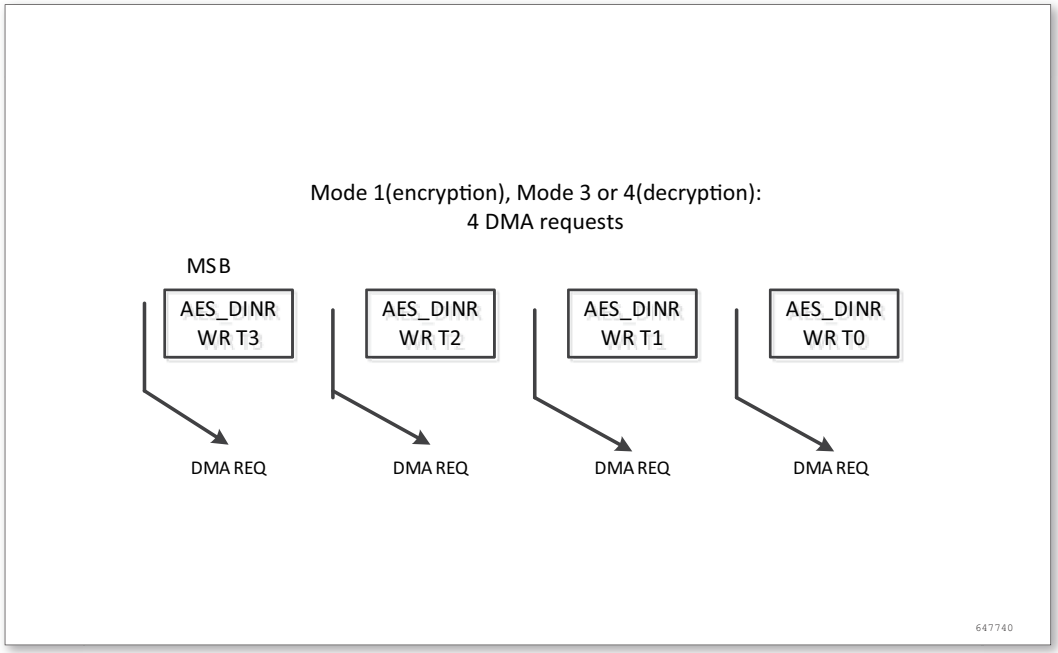

Figure 274. DMA Request and Data Transfer (AES_IN) at Input Stage

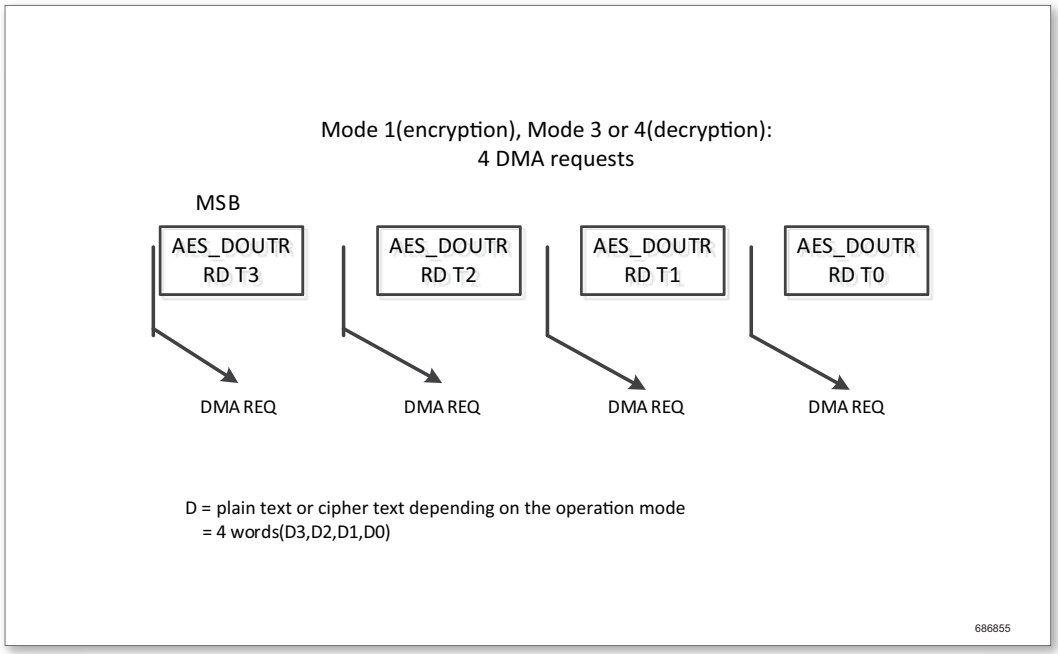

Figure 275. DMA Request (AES_OUT) at Output Stage

24.9 Error flag

The RDERR flag in the AES_SR register is set to ’1’ when an unexpected read is detected at the calculation stage or input stage. The WRERR flag in the AES_SR register is set to ’1’ when an unexpected write is detected in the output or calculation stage. The flag can be cleared by setting relevant bits in the AES_CR register (the CCFC bit for clearing the CCF flag and the ERRC bit for clearing the WERR and RDERR flags). If the ERRIE bit in the AES_CR register has been set previously, an interrupt may be generated when one

of the error flags is set. If the ERRIE bit in the AES_CR register has been set previously, an interrupt may be generated when one of the error flags is set. If an error is detected, AES continues to process the data without being interrupted by hardware.

24.10 Processing time

The table below summarizes the time required to process a 128-bit block in each operating mode.

Table 77. Processing Time in Various Chaining Modes

Key length	Operating mode	Chaining mode	Input stage	Calculation stage	Output stage	Total
128bit	Mode 1: encryption	ECB,CBC,CTR,CFB,OFB	8	11	4	23
	Mode 2: key expansion	-	-	11	-	11
	Mode 3: decryption	ECB,CBC,CTR,CFB,OFB	8	11	4	23
	Mode 4: key expansion+decryption	ECB,CBC,CFB,OFB	8	23	4	35
192bit	Mode 1: encryption	ECB,CBC,CTR,CFB,OFB	8	13	4	25
	Mode 2: key expansion	-	-	13	-	13
	Mode 3: decryption	ECB,CBC,CTR,CFB,OFB	8	13	4	25
	Mode 4: key expansion+decryption	ECB,CBC,CFB,OFB	8	27	4	39

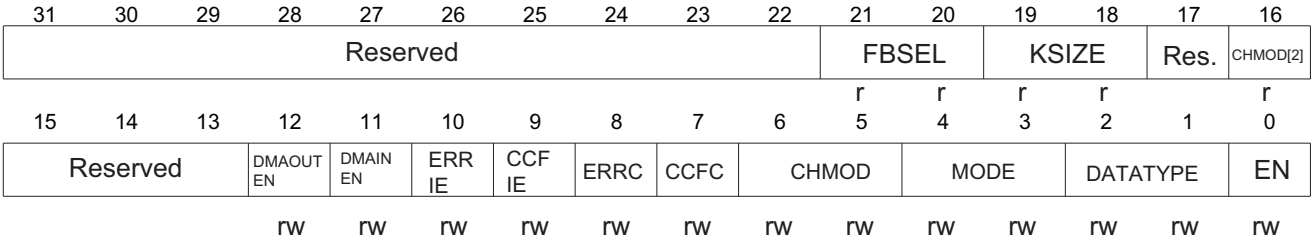
24.12.1 AES contro register(AES_CR)

Offset address:0x00

Reset value:0x0000 0000



Bit	Field	Type	Reset	Description
31: 22	Reserved			Always read as 0.
21: 20	FBSEL	r	0x00	Feedback size; valid only in CFB and OFB modes. 00: 1bit 01: 8bit 10: 64bit 11: 128bit

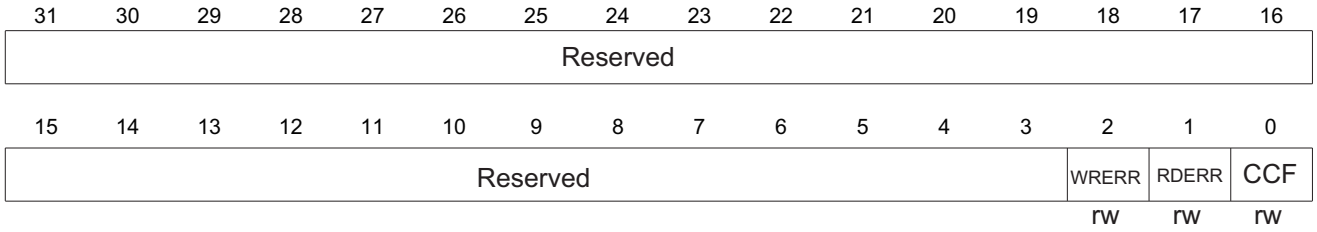
Bit	Field	Type	Reset	Description
19: 18	KSIZE	r	0x00	Key size 00: 128bit 01: 192bit 10: 256bit 11: Reserved
17	Reserved			Always read as 0.
16	CHMOD[2]	r	0x00	Combination with of CHMOD1:0, to select AES chaining mode 000: ECB 001: CBC 010: CTR 100: CFB 101: OFB other: Reserved
15: 13	Reserved			Always read as 0.
12	DMAOUTEN	rw	0x00	DMA management during enable data output stage 0: Disable DMA (in the data output stage) 1: Enable DMA (in the data output stage) If the DMAOUTEN bit is set, a DMA request is generated at the output data stage in Mode 1, 3 or 4. This bit has no effect in Mode 2 (key expansion).
11	DMAINEN	rw	0x00	DMA management during enable data input stage 0: Disable DMA (in the data input stage) 1: Enable DMA (in the data input stage) If the DMAINEN bit is set, a DMA request is generated at the data input stage in Mode 1, 3 or 4. This bit has no effect in Mode 2 (key expansion).
10	ERRIE	rw	0x00	Error interrupt enable An interrupt is generated if at least one of the two flags, RDERR or WRERR, is set. 0: Error interrupt disabled 1: Error interrupt enabled
9	CCFIE	rw	0x00	CCF flag interrupt enable An interrupt is generated if the CCF flag is set. 0: CCF disables interrupt 1: CCF enables interrupt
8	ERRC	rw	0x00	Error clear Clear the RDERR and WRERR flags by writing 1 to this bit. This bit is always low.
7	CCFC	rw	0x00	Calculation completion flag clear Clear the CCF flag by writing 1 to this bit. This bit is always low.

Bit	Field	Type	Reset	Description
6: 5	CHMOD	rw	0x00	AES chaining mode (CHMOD1:0 combined with CHMOD3 of Bit 16 to select chaining mode) 000: Electronic code book (ECB) 001: Cipher block chaining (CBC) 010: Counter mode (CTR) 100: Ciphertext feedback mode (CFB) 101: Output feedback mode (OFB) AES chaining mode can only be changed when AES is disabled; writing these bits is disabled when AES is enabled, to avoid unpredictable AES behavior.
4: 3	MODE	rw	0x00	AES operating mode 00: Mode 1: encryption 01: Mode 2: key expansion 10: Mode 3: decryption 11: Mode 4: key expansion + decryption The operating mode can only be changed if AES is disabled. Writing these bits is disabled if AES is enabled, to avoid unpredictable AES behavior. Mode 4 is disabled if CTR mode is selected; if the software attempts to configure Mode 4 for the CTR mode, it will be forced into Mode 3.
2: 1	DATATYPE	rw	0x00	Data type selection (for data input and data output in encrypted blocks) 00:32-bit data; no exchange. 01: 16-bit data or halfword. In short, each halfword is exchanged. For example, If one of the four 32-bit data, written to the AES_DINR register, is 0x764356AB, the value sent to the encrypted block is 0x56AB7643. 10: 8-bit data or byte. In summary, all bytes are swapped. For example, if one of the four 32-bit data, written to the AES_DINR register, is 0x764356AB, the value given to the encrypted block is 0xAB564376. 11: 1-bit data. In summary, all bytes are swapped. For example, if one of the four 32-bit data, written to the AES_DINR register, is 0x764356AB, the value given to the encrypted block is 0xD56AC26E. The data type selected can only be changed when AES is disabled; writing these bits is disabled when AES is enabled, to avoid unpredictable AES behavior.

Bit	Field	Type	Reset	Description
0	EN	rw	0x00	AES enable 0: Disable AES 1: Enable AES AES can be reinitialized at any time by resetting this bit: when EN is set, AES is ready to start processing a new block. This bit is cleared by hardware when the AES calculation is completed in Mode 2 (key expansion).

24.12.2 AES status register(AES_SR)

Offset address:0x04 Reset value:0x0000 0000



Bit	Field	Type	Reset	Description
31: 3	Reserved			Reserved, read as 0
2	WRERR	rw	0x00	Write error flag This bit is set to ’1’ by hardware when an unexpected write to the AES_DINR register is detected (in the calculation or data output stage). An interrupt is generated if the ERRIE bit has beeen previously set in the AES_CR register; this flag has no effect on AES that continues operating even if WERR is set. It is cleared by software through setting the ERRC bit in the AES_CR register to ’1’. 0: No write error detected 1: Write error detected
1	RDERR	rw	0x00	Read error flag This bit is set to ’1’ by hardware when an unexpected read to the AES_DOUTR register is detected (in the calculation or data output stage). An interrupt is generated if the ERRIE bit has beeen previously set in the AES_CR register; this flag has no effect on AES that continues operating even if RDERR is set to ’1’. It is cleared by software through setting the ERRC bit in the AES_CR register to ’1’. 0: No read error detected 1: Read error detected

Bit	Field	Type	Reset	Description
0	CCF	rw	0x00	Calculation completion flag When the calculation is completed, this bit is set to '1' by hardware. An interrupt is generated if the CCFIE bit has been previously set in the AES_CR register. This bit is cleared by software through setting the CCFC bit in the AES_CR register. 1: Calculation completed 0: Calculation not completed Note: This bit is only valid when DMAOUTEN = 0, and can be held high when DMA_EN = 1.

24.12.3 AES data input register(AES_DINR)

Offset address:0x08 Reset value:0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

KEYR0															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit	Field	Type	Reset	Description
31: 0	KEYR0	rw	0x0000 0000	Data output register(LSB key) This register must be written before the EN bit in the AES_CR register is set to '1' : In Mode 1 (encryption), Mode 2 (key export) and Mode 4 (key export + decryption), the value to be written represents the encryption key from the LSB, namley, Key [31:0]. In Mode 3 (decryption), the value to be written represents the decryption key starting from LSB, namely, Key [31:0]. When an encryption key is written to the register in this decryption mode, the encrypted value will be returned by reading it before AES is enabled, and the expanded key will be returned if it is read after the CCF flag is set. The unpredictable value will be returned if this register is read and AES is enabled. Note: This register contains no expanded key in Mode 4 (key extension + decryption), but always contains the encryption key value.

25 System configuration controller (SYSCFG)

System configuration controller (SYSCFG)

The device is provided with a set of system configuration registers, with the main functions as follows:

- The remapping section covers the TIM16 and TIM17, and UART1 and DMA trigger sources of ADC to other different DMA channels.
- Management device connected to the external interrupts of GPIO port.
- Remapping the memory to the code starting area.
- Pin configuration for external interrupt.

25.1 SYSCFG register description

Table 80. Summary of SYSCFG Register

Offset	Acronym	Register Name	Reset	Section
0x00	SYSCFG_CFGR	SYSCFG configuration register	0x0000000X	section 25.1.1
0x08	SYSCFG_EXTICR1	External interrupt configuration register 1	0x00000000	section 25.1.2
0x0C	SYSCFG_EXTICR2	External interrupt configuration register 2	0x00000000	section 25.1.3

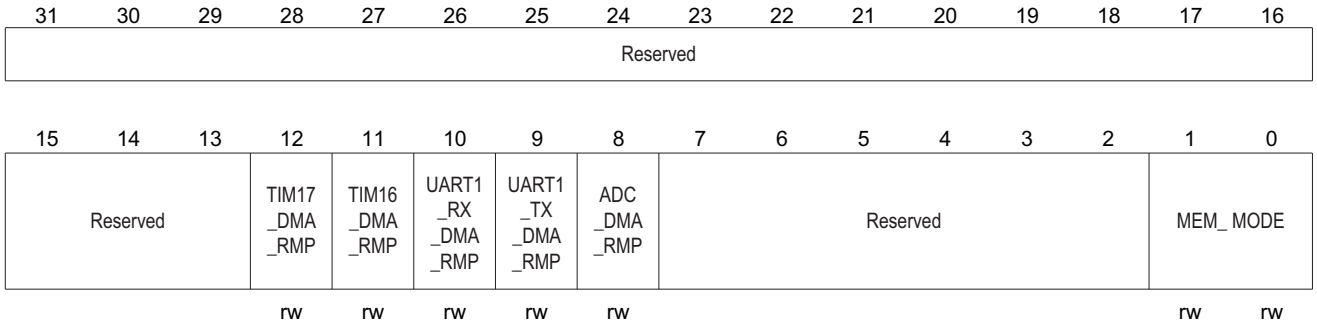
0x14	SYSCFG_EXTICR4	External interrupt configuration register 4	0x00000000	section 25.1.5

25.1.1 SYSCFG configuration register (SYSCFG_CFGR)

This register is dedicated to configuring memory start area mapping and DMA request remapping, with two control bits of configurable memory start address (0x0000 0000) storage area type, these two control bits can be configured by software, to mask BOOT selection. After reset, these two control bits represent the actual BOOT mode configuration.

Offset address: 0x00

Reset value: 0x0000 000X(X: the selection control bit of the actual BOOT mode)



Bit	Field	Type	Reset	Description
31 : 13	Reserved			Always read as 0.
12	TIM17_DMA _RMP	rw	0x00	TIM17 DMA request remapping bit This bit is set and cleared by the software, controlling the remapping of TIM17 DMA channel requests. 0: No remapping(TIM17_CH1 and TIM17_UP DMA request mapped on DMA Channel 1) 1: Remapping (TIM17_CH1 and TIM17_UP DMA request mapped on DMA Channel 2)
11	TIM16_DMA _RMP	rw	0x00	TIM16 DMA request remapping bit This bit is set and cleared by the software.controlling the remapping of TIM16 DMA channel requests. 0: No remapping(TIM16_CH1 and TIM16_UP DMA request mapped on DMA Channel 3) 1: Remapping (TIM16_CH1 and TIM16_UP DMA request mapped on DMA Channel 4)
10	UART1_RX _DMA_RMP	rw	0x00	UART1_RX DMA request remapping bit This bit is set and cleared by the software, controlling the remapping of UART1_RX DMA channel requests. . 0: No remapping(UART1_ RX DMA request mapped on DMA Channel 3) 1: Remapping (UART1_ RX DMA request mapped on DMA Channel 5)
9	UART1_TX _DMA_RMP	rw	0x00	UART1_TX DMA request remapping bit This bit is set and cleared by the software, controlling the remapping of UART1_TX DMA channel requests. 0: No remapping(UART1_TX DMA request mapped on DMA Channel 2) 1: Remapping (UART1_TX DMA request mapped on DMA Channel 4)

Bit	Field	Type	Reset	Description
8	ADC_DMA_RMP	rw	0x00	ADC DMA request remapping bit This bit is set and cleared by the software, controlling the remapping of ADC DMA channel requests. 0: No remapping(ADC DMA request mapped on DMA Channel 1) 1: Remapping (ADC DMA request mapped on DMA Channel 2)
7 : 2	Reserved			Always read as 0.
1 : 0	MEM_MODE	rw	0x00	Memory selection bit These bits are set and cleared by the software, controlling the internal mapping of the memory to address 0x0000 0000. When being reset, these bit values are determined by the BOOT0 pin configuration value and the nBOOT1 bit value. x0: main flash memory mapped to 0x0000 0000 01: System flash mapped to 0x0000 0000 11: Embedded RAM mapped to 0x0000 0000

26 Device electronic signature (Device)

Device electronic signature (Device)

The electronic signature is stored in the System memory area in the Flash memory module, and can be read using the JTAG/SWD or the CPU. It contains factory-programmed identification data that allow the user firmware or other external devices to automatically match microcontrollers with different configurations.

26.1 Memory size registers

26.1.1 Unique device ID register (96 bits)

The unique device identifier is ideally suited:

- for use as serial numbers (for example USB string serial numbers or other end applications).
- for use as security keys in order to increase the security of code in Flash memory while using and combining this unique ID with software cryptographic primitives and protocols before programming the internal Flash memory.
- to activate secure boot processes, etc.

The 96-bit unique device identifier provides a reference number which is unique for any device and in any context. These bits can never be altered by the user.

The 96-bit unique device identifier can also be read in single bytes (8 bits) /half-words (16 bits) /full words (32 bits) in different ways and then be concatenated using a custom algorithm.

26.2 UID register description

Table 81. Memory Capacity Register Description Overview

Offset	Acronym	Register Name	Reset	Section
0x00	UID1	Unique identification code	0xXXXXXXXX	section 26.2.1

27 Debug support(DBG)

Debug support(DBG)

27.1 Overview

The core of the series contains hardware debugging modules for complex debugging operations. The hardware debugging modules allow the core to be stopped either on a given instruction fetch (breakpoint) or data access (watchpoint).

When stopped, the core's internal state and the system's external state may be examined. Once examination is completed, the core and the system may be restored and program execution resumed.

The hardware debugging module is used by the debugger for relevant operations when it is connected to and used for debugging the microcontroller of the series.

Support:

- Serial debug interface

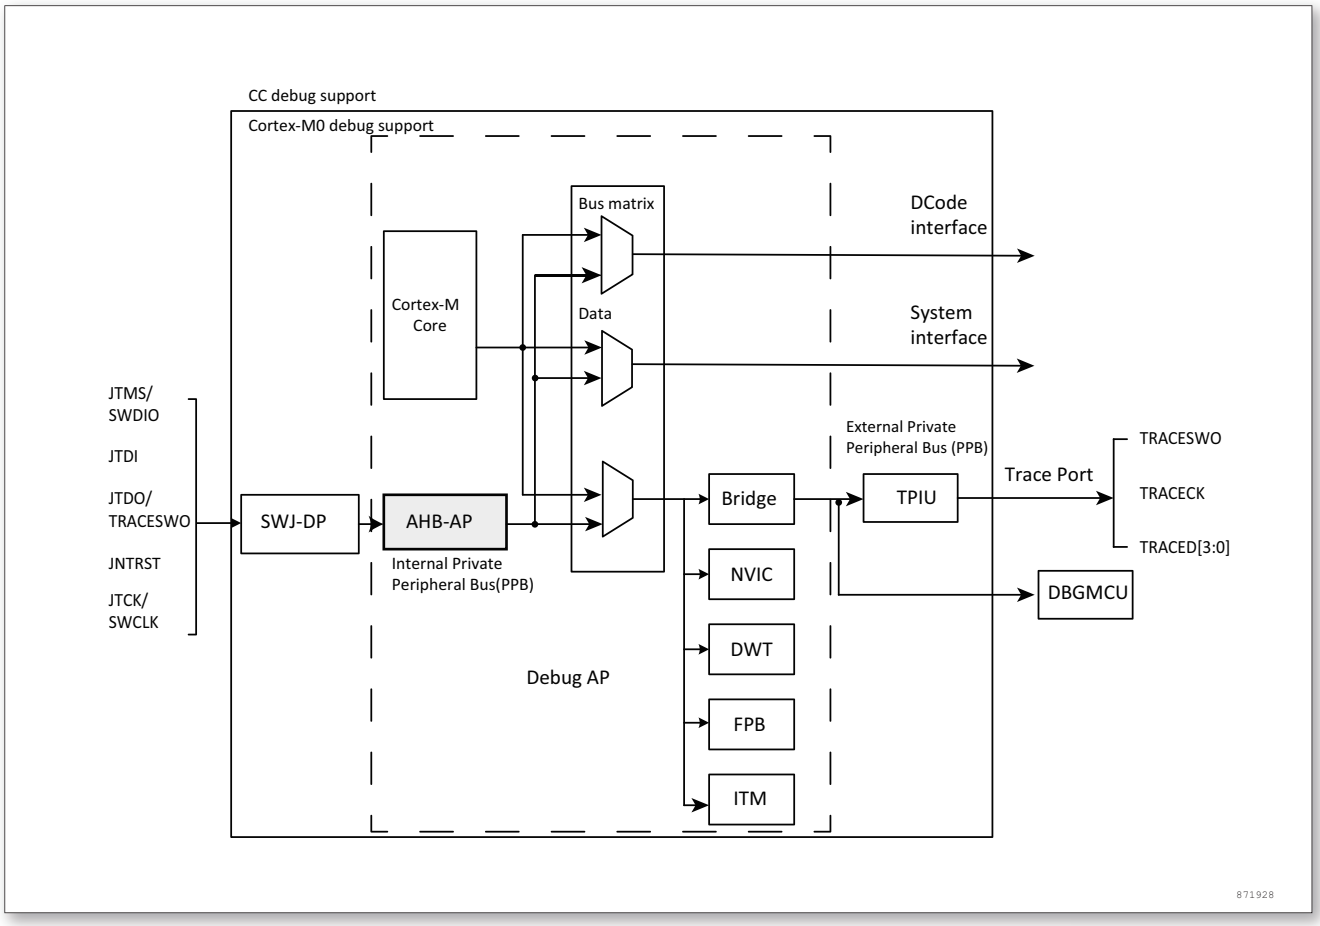

Figure 276. Block Diagram of MM32 Series Level and CPU Level Debug Support

The core provides integrated on-device debug support. It is comprised of:

- SW-DP: : serial debug port
- AHP-AP: AHB access port
- ITM: Instrumentation trace macrocell
- FPB: Flash patch breakpoint
- DWT: Data watchpoint trigger
- TPUI: Trace port unit interface

27.2 Pinout and debug port pins

The device microcontroller is available in various packages with different numbers of available pins. As a result, some functionality related to pin availability may differ between packages.

27.2.1 SWD debug port pins

2 ordinary I/O ports of the device are used as the SW-DP interface pins. These pins are available on all packages.

Table 82. SWJ Debug Port Pins

SWJ-DP pin name	SW debug interface		Pin assignment
	Type	Debugging function	
SW SW debug interface	Input/output	Serial data input/output	PA13
SWCLK	Input	Serial clock	PA14

27.2.2 Internal pull-up and pull-down on SWD pins

It is necessary to ensure that the SWD input pins are not floating since they are directly connected to D flip-flops to control the debug mode features. Special care must be taken with the SWCLK pin which is directly connected to the clock of some of these flip-flops.

To avoid any uncontrolled I/O levels, the device embeds internal pull-ups and pull-downs on the SWD input pins:

- SWDIO: Internal pull-up
- SWCLK: Input with pull-down

The software can use these I/Os as ordinary I/Os.

27.3 ID codes and locking mechanism

There are several ID codes inside the device.

27.3.1 MCU device ID code

The MCU integrates an MCU ID code. This ID identifies the MCU part number and the die revision. It is part of the DBG_MCU component and is mapped on the external APB bus. This code is accessible using the SW debug port (2 pins) or by the user code.

DBGMCU_IDCODE

Address: 0x40013400 Only 32-bits access supported.

Read-only =0xXXXXXXXX, where X is a bit with undefined content.

27.4 SW debug port

27.4.1 SW protocol introduction

This synchronous serial protocol uses two pins:

- SWCLK: clock from host to target
- SWDIO: bidirectional

The protocol allows two banks of registers (DPACC registers and APACC registers) to be read and written to. Bits are transferred LSB-first on the wire. For SWDIO bidirectional management, the pin must be pulled-up on the board (100 KΩ recommended). Each time the direction of SWDIO changes in the protocol, a turnaround time is inserted where the line is not driven by the host nor the target. By default, this turnaround time is one bit time, however, this can be adjusted by configuring the SWCLK frequency.

27.4.2 SW protocol sequence

Each sequence consist of three phases:

- Packet request (8 bits) transmitted by the host
- Acknowledge response (3 bits) transmitted by the target
- Data transfer phase (33 bits) transmitted by the host or the target

Table 84. Packet Request (8-bit)

Bit	Name	Description
0	Start	Must be ’1’
1	APnDP	0: DP Access 1: AP Access
2	RnW	0: Write Request 1: Read Request
4:3	A(3: 2)	Address field of the DP or AP registers
5	Parity	Single bit parity of preceding bits
6	Stop	0

Bit	Name	Description
7	Park	Not driven by the host. Must be read as '1' by the target because of the pull-up

Refer to the CPU TRM (Technical Reference Manual) for a detailed description of DPACC and APACC registers.

The packet request is always followed by the turnaround time (default 1 bit) where neither the host nor target drives the line.

Table 85. Packet Request (3-bit)

Bit	Name	Description
0..2	ACK	001: Fault 010: Wait 100: OK

The ACK must be followed by a turnaround time only if it is a READ transaction or if a WAIT or FAULT acknowledge has been received.

Table 86. Packet Request (33-bit)

Bit	Name	Description
0..31	WDATA/RDATA	Write or read data
32	Parity	Single parity of the 32 data bits

The DATA transfer must be followed by a turnaround time only if it is a READ transaction.

27.4.3 SW-DP state machine (Reset, idle states, ID code)

The state machine of the SW-DP has an internal ID code which identifies the SW-DP. It follows the JEP-106 standard.

The SW-DP state machine is inactive until the debugger reads this ID code.

- The SW-DP state machine is in RESET STATE either after power-on reset, or after the DP has switched from JTAG to SWD or after the line is high for more than 50 cycles.
- The SW-DP state machine is in IDLE STATE if the line is low for at least two cycles after RESET state.
- After RESET state, it is mandatory to first enter into an IDLE state AND to perform a READ access of the DP-SW ID CODE register. Otherwise, the debugger will issue a FAULT acknowledge response on another transactions.

27.4.4 DP and AP read/write accesses

- Read accesses to the DP are not posted: the target response can be immediate (if ACK=OK) or can be delayed (if ACK=WAIT).
- Read accesses to the AP are posted. This means that the result of the access is re-

turned on the next transfer. If the next access to be done is NOT an AP access, then the DP-RDBUFF register must be read to obtain the result.

- The READOK flag of the DP-CTRL/STAT register is updated on every AP read access or RDBUFF read request to know if the AP read access was successful.
- The SW-DP implements a write buffer (for both DP and AP writes), that enables it to accept a write operation even when other transactions are still outstanding. If the write buffer is full, the debugger acknowledge response is ”WAIT”. With the exception of IDCODE read or CTRL/STAT read or ABORT write which is accepted even if the write buffer is full.
- Because of the asynchronous clock domains SWCLK and HCLK, two extra SWCLK cycles are needed after a write transaction (after the parity bit) to make the write effective internally. These cycles should be applied while driving the line low (IDLE state). This is particularly important when writing the CTRL/STAT for a power-up request. If the next transaction (requiring a power-up) occurs immediately, it will fail.

27.4.5 SW-DP register

Access to these registers are initiated when APnDP=0.

A(3: 2)	Read/write	CTRLSEL bit of SELECT register	Register	Description
00	Read		IDCODE	It is set to 0x1BA01477 (identifies the SW-DP)
00	Write		ABORT	
01	Read/Write	0	DP-CTRL/STAT	Request a system or debug power-up; configure the transfer operation for AP accesses; control the compare and verify operations; read some status flags (overrun, power-up acknowledges)
01	Read/Write	1	WIRE CONTROL	Configure the physical serial port protocol (like the duration of the turnaround time).
10	Read		READ RESEND	Enables recovery of the read data from a corrupted debugger transfer, without repeating the original AP transfer.
10	Write		SELECT	Select the current access port and the active 4-word register window.
11	Read/Write		READ BUFFER	This read buffer is useful because AP accesses are posted (the result of a read AP request is available on the next AP transaction). This read buffer captures data from the AP, presented as the result of a previous read, without initiating a new transaction

27.4.6 SW-AP register

Access to these registers are initiated when APnDP=1.

There are many AP Registers addressed as the combination of:

- A[3:2]

- The current value of the DP SELECT register

27.5 MCU debug module (MCUDBG)

The MCU debug module assists the debugger with the following features:

- Low power mode
- Provide timer at breakpoint, and enable the clock control of watchdog
- Control the assignment of trace pin

27.5.1 Debugg support in low power mode

To enter low-power mode, the instruction WFI or WFE must be executed. The MCU implements several low-power modes which can either deactivate the CPU clock or reduce the power of the CPU. The core does not allow FCLK or HCLK to be turned off during a debug session. As these are required for the debugger connection, during a debug, they must remain active. The MCU integrates special means to allow the user to debug code in low-power modes.

For this, the debugger host must first set some debug configuration registers to change the low-power mode behavior:

- In Sleep mode, DBG_SLEEP bit of DBGMCU_CR register must be previously set by the debugger. This will feed HCLK with the same clock that is provided to FCLK (system clock previously configured by the software).
- In Stop mode, the bit DBG_STOP must be previously set by the debugger. This will enable the internal RC oscillator clock to feed FCLK and HCLK in STOP mode.

27.5.2 Debug MCU configuration register

This register allows the configuration of the MCU under DEBUG. This concerns:

- Low-power mode support
- Timer and watchdog counter support
- Trace pin assignment

This DBGMCU_CR is mapped on the External APB bus at address 0x40013404. It is asynchronously reset by the PORESET (and not the system reset). It can be written by the debugger under system reset.

If the debugger host does not support these features, it is still possible for the user software to write to these registers.

27.6 Description of DBG Register

Table 88. Summary of DBG Register

Offset	Acronym	Register Name	Reset	Section
0x00	DBG	DBG Control Register	0x00000000	section 27.6.1

27.6.1 DBG Control Register(DBG_CR)

Address: 0x40013404 Only 32-bits access supported.

POR Reset: 0x0000 0000 (not reset by system reset)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved		DBG_TIMx_STOP				DBG_WWDG_STOP	DBG_IWDG_STOP	Reserved					DBG_STANDBY	DBG_STOP	DBG_SLEEP
		w	w	w	w	w	w						w	w	w

Bit	Field	Type	Reset	Description
31:14	Reserved			Always read as 0.
13:10	DBG_TIMx_STOP	w	0x00	TIMx counter stopped when core is halted 0: The clock of the involved Timer Counter is fed even if the core is halted 1: 1: The clock of the involved Timer counter is stopped when the core is halted
9	DBG_WWDG_STOP	w	0x00	Debug window watchdog stopped when core is halted 0: The window watchdog counter clock continues even if the core is halted 1: The window watchdog counter clock is stopped when the core is halted
8	DBG_IWDG_STOP	w	0x00	Debug independent watchdog stopped when core is halted 0: The watchdog counter clock continues even if the core is halted 1: The watchdog counter clock is stopped when the core is halted
7:3	Reserved			Always read as 0.
2	DBG_STANDBY	w	0x00	Debug Standby mode 0: (FCLK=Off, HCLK=Off) The whole digital part is unpowered. From software point of view, exiting from Standby is identical than fetching reset vector (except a few status bit indicated that the MCU is resuming from Standby) 1: (FCLK=On, HCLK=On) In this case, the digital part is not unpowered and FCLK and HCLK are provided by the internal RC oscillator which remains active. In addition, the MCU generate a system reset during Standby mode so that exiting from Standby is identical than fetching from reset

Bit	Field	Type	Reset	Description
1	DBG_STOP	w	0x00	Debug Stop mode 0: (FCLK=Off, HCLK=Off) In STOP mode, the clock controller disables all clocks (including HCLK and FCLK). When exiting from STOP mode, the clock configuration is identical to the one after RESET (CPU clocked by the 8 MHz internal RC oscillator (HSI)). Consequently, the software must reprogram the clock controller to enable the PLL, the Xtal, etc. 1: (FCLK=On, HCLK=On) In this case, when entering STOP mode, FCLK and HCLK are provided by the internal RC oscillator which remains active in STOP mode. When exiting STOP mode, the software must reprogram the clock controller to enable the PLL, the Xtal, etc. (in the same way it would do in case of DBG_STOP=0)
0	DBG_SLEEP	w	0x00	Debug Sleep mode 0: (FCLK=On, HCLK=Off) In Sleep mode, FCLK is clocked by the system clock as previously configured by the software while HCLK is disabled. In Sleep mode, the clock controller configuration is not reset and remains in the previously programmed state. Consequently, when exiting from Sleep mode, the software does not need to reconfigure the clock controller. 1: (FCLK=On, HCLK=On) In this case, when entering Sleep mode, HCLK is fed by the same clock that is provided to FCLK (system clock as previously configured by the software).

28 Revision history

Revision history

Table 89. Revision History

Date	Rversion	Changes
2019/08/06	Rev1.15	Modify the typo at the memory and bus architecture
2019/07/23	Rev1.14	SPI_EXTCTL is only valid when the DW8_32 bit is ’0’
2019/07/16	Rev1.13	The minimum UART BRR register is 4
2019/07/09	Rev1.12	Modify the comparator mode parameter description
2019/06/13	Rev1.11	Modify CSR defaults
2019/05/09	Rev1.10	Modify port mode configuration Correct the break in the advanced timer and the configuration bit (DTG) of dead time generator in dead-time register (BDTR)
2019/04/16	Rev1.09	Modify the adc calculation formula
2019/01/10	Rev1.08	Modify PWR description
2018/12/22	Rev1.08	Change ”CC1S = 01 in the TIMx_CCR1 register” in the input capture section to ”CC1S = 01 in the TIMx_CCMR1 register” in the TIMX_16 bit Functional Description. Replace ”capture” with ”capture” in TIM1/8 section. Change ”CC1S = 01 in the TIMx_CCR1 register” in the input capture section to ”CC1S = 01 in the TIMx_CCMR1 register” in the TIM1/8 Functional Description. Change the incorrect writing ”IMx_CR1” to ”TIMx_CR1” in synchronization part of the TIM1/8 TIMx timer and external trigger. DIV_Mantiss shall not be 0 in UART_BRR.
2018/12/20	Rev1.07	Change UART_CSR to UART current status register
